advised for that dangerous malady. (See *art. STOMATITIS*, § 31–33.)

47. *II. Gonorrhœal vulvitis* (§ 38) is treated as follows by M. RICORD and Mr. ACTON. In the commencement a soothing plan should be employed, and separation of the surfaces attempted, followed by lotions of nitrate of silver, in the proportion of ʒj. to ʒij. of distilled water, and by warm baths. If the inflammation has gained the deeper tissues, the soothing plan should be adopted, or leeches should be applied to the groins. If a phlegmonous condition of parts occurs, depletions should be chiefly relied on; and the moment that an abscess is formed an opening should be made into it, in order to prevent the pus from burrowing through the cellular tissue. When urethritis is much complained of, cubebs and the balsams, with demulcents, are then required. Afterward, balsams and lotions of the solution of the nitrate of silver should be prescribed.

48. *I. The consequences of the several forms of vulvitis* must be treated with reference not only to their actual states, but also to the circumstances, features, and complications of individual cases. General therapeutical principles will guide the physician in respect of these as well as of other morbid conditions, recollecting, however, as respects the most of them, that strict attention to ablations by suitable means; to the digestive, assimilative, depurating, and excreting functions; and to the promotion of constitutional power, and of vital resistance to the extension of disease, are the surest principles of successful practice.

49. *III. STRUCTURAL AND OTHER LESIONS OF THE VULVA.*—These consist chiefly of *hypertrophy of the nymphæ*, of *tumours of the clitoris*, *thrombus* or effusion of blood in the labia after injuries or parturition, *fistula*, *cancer*, *herma*, *elephantiasis* of the vulva or of the nymphæ, *tumours* or *cysts*—erectile, sebaceous, follicular, or others—the growth of *hair within the vulva*, &c. These concern the surgeon rather than the physician, and require no remarks from me. The only exception may be made in regard of *hypertrophy of the nymphæ*, which may take place to so great an extent as to require their extirpation. In unmarried females, advanced in age, this change has undoubtedly proceeded from masturbation. But in very young females, to whom this vice could not be imputed, and also in children, the nymphæ are sometimes so greatly developed as to protrude far below the labia majora. Of this state of parts I have seen several instances. In one case which came before me, the very enlarged and prolonged nymphæ were extirpated. The hæmorrhage was very considerable, but recovery was complete. The clitoris may be enlarged as well as the nymphæ; and in such cases the enlargement is probably owing to masturbation. These parts have been observed by LARREY, GILBERT, CLOT-BEY, TALRICH, and others, to have been the seats of elephantiasis; the tumours which resulted having been as large as a child's head. M. VELPEAU has referred to several cases of this nature, which, however, are not rare in Egypt and other parts of Africa.

**VEINS, DISEASES OF.**—1. This order of circulating vessels has not received that share of attention and research which it deserves in several states of disease, either implicating it more especially, or affecting the frame generally, and changing more or less not merely the blood circulating in it, but the whole mass of blood supplying all the organs and tissues of the body. Hence alterations of these vessels should not be viewed with reference to themselves only, and as

local changes merely, but with a due recognition of the effects produced by them on the blood, and, through the blood, upon the whole frame. Even this apparently comprehensive view is not sufficient, it is only one aspect in which this subject should be studied—one side of the object—for another presents itself to the experienced and searching eye, viz, the many noxious agents, and the numerous local changes and structural lesions affecting primarily the several tissues and organs, frequently altering either the blood in these parts, or the veins originating in them, or even both, successively contaminating the blood and circulating systems, and ultimately altering the vital cohesion and the ultimate organization of all parts of the living body.

2 It would be impossible, even were it necessary, to consider the diseases of veins, especially in connexion with those of the blood, with that amplitude which I might desire or others expect. This subject can be viewed only in its more practical and important relations, at this place. The full consideration which I have bestowed on the several matters and topics intimately connected with diseases of the blood and circulating organs and vessels, and on the treatment of them under their respective heads, in the early parts of the work, prevents me from attempting more at this place than to notice what has not already come under discussion.

3. It is chiefly to JOHN HUNTER that we are indebted for the earliest and best information respecting diseases of the veins, and especially as to the treatment most appropriate to inflammation of them. Since his time the researches and works of BAILLIE, HODGSON, CRUVEILHIER, MECKEL, BRESCHET, DAVIS, DANCE, LEE, GENDRIN, RIBES, ARNOTT, and others, have tended most essentially to advance our knowledge of these important subjects. Diseases of the veins resemble those of the *lymphatics* and *arteries* (see those articles) in some respects, and differ from them in others, particularly as regards the constitutional symptoms. The veins never exhibit an alteration in all respects similar to aneurism, because their coats yield equally to pressure, and are not subject to the forcible impetus of the blood, besides, their inner coats are more susceptible of dilatation without rupture than those of the arteries; they are, however, more subject to inflammation and varicose dilatation than the latter vessels.

4. Ossific formations, which are so often met with in arteries, are seldom found in veins. The difference of texture is not sufficient to account for this; for, as M ANDRAL remarks, the structure of the pulmonary artery is the same as that of the aorta, and the right side of the heart is organized precisely as the left; and yet ossifications are much more frequent in the aorta and left side of the heart than in the pulmonary artery and right side. The more abundant supply of ganglial nerves to the arteries than to the veins may, perhaps, tend to create a difference as to the nature and frequency of diseases of these two orders of vessels. The constitution of the blood, and peculiarities of the circulation in each, may also contribute to diversify their maladies. The circumstance of the blood being oftener coagulated and organized in the veins than in the arteries may be chiefly imputed to this latter cause, and to the more frequent occurrence of inflammation in the former vessels. Pus is more com-

monly found in the veins than in the arteries; this is owing to three causes: 1st, to the greater frequency of inflammation of veins; 2d, to the circumstance of this morbid secretion being carried into the veins by absorption; and, 3d, to the probable metamorphosis or alteration of the pus-globules before they reach the arterial circulation. Perhaps the second and third causes are the most influential.

5 The constitutional effects of diseases of the veins, and the consequences of inflammation of them, differ very considerably from those which characterize the maladies of the other orders of vessels composing the vascular system. but the differences are chiefly apparent in acute inflammations of these vessels, as will be observed upon referring to what has been stated respecting these diseases.

6. I. INFLAMMATION OF VEINS—SYNON *Phlebitis* (from φλέψ, a vein) *Aderentzündung Blutaderentzündung*, Germ. *Phlébite*, Fr.

CLASSIF.—III. CLASS, 1. ORDER (*Author in Preface*).

7 DEFINIT.—*Tenderness, tension, acute pain, and a knotted, cord-like swelling or hardness in the course of a vein or veins, sometimes with discoloration, when the veins are superficial, extending both to and from the centre of circulation, with symptomatic fever, which often passes into an adynamic state, with indications of contamination of the blood, or purulent formations in the viscera or other parts*

8. The *pathological anatomy* of phlebitis will be more fully shown in the sequel; but it may be stated at this place that inflammation of veins occasions, 1st. The formation of coagula adhering, by means of the lymph exuded from the inflamed surface, to the internal membrane of the vessel; 2d. The secretion of pus, which may be surrounded by a false membrane, or by coagulated lymph, or be contained in coagula adhering to the internal surface of the vessel; 3d. The secretion of pus, which is not surrounded either by plastic lymph, or by a coagulum, but which has a free access to the current of circulation; and, 4th. The secretion of an ichorous or sanious fluid from the inflamed inner membrane, which rapidly mingles with and contaminates the blood, and generally produces rapid and fatal changes of the structures. Instead, therefore, of viewing phlebitis, as heretofore, to consist of only *two* principal forms, viz., the *adhesive* and the *suppurative*, the latter being either confined or free, I would add a *third*, the *ichorous* or *poisonous*.

9. *Inflammation of veins* is of the greatest importance as respects both the local lesions and the consequent contamination of the blood. It is much more frequently seen than inflammation of arteries. Its seat is the cellular tissue of the vein, and the circular fibrous coat, in as far as the latter exhibits any degree of redness or vascularity; and its products are deposited in both these, and in the non-vascular or internal lining membrane extending into the canal of the vessel. It more frequently is *acute* than *chronic*, the former being distinguished by an exudation on the inner surface of the vessel. When phlebitis—inflammation of the coats of the vessel—is the primary disease, the changes of the blood, and other alterations within the inflamed vein, are consequences of this inflammation, these changes being secondary. But when the blood in a vein is coagulated, or is otherwise remarkably altered or poi-

oned, it may, in such a state, irritate the internal membrane of the vein, inflame it, or all the coats of the vessel, the phlebitis being thus consecutive or secondary. The disease may be seated in a single vein, or extended to several, or even to many, whether it be thus primary or consecutive.

10. JOHN HUNTER first demonstrated the pathological changes and the consecutive phenomena of phlebitis. Many years afterward, SASSE, B. TRAVERS, ABERNETHY, HODGSON, and BRESCHE directed their attention to this disease; and more recently RIBES, ARNOTT, DANCE, DAVIS, R. LEE, MARÉCHAL, BOULLAUD, CRUVEILHIER, VELPEAU, BLANDIN, ROKITANSKY, and others, have contributed facts and opinions respecting it. Nevertheless the subject is by no means exhausted; for there still remain various topics connected with it, both pathologically and therapeutically, requiring farther elucidation and confirmation.

11. i. THE CAUSES OF PHLEBITIS.—Inflammations of the veins are much more frequent in the male than in the female sex, if phlebitis consequent upon parturition be excluded from the account, and in ages from fifteen years to fifty. This greater frequency in males, and in the active periods of life, is probably owing to a greater exposure to injuries and other exciting causes in this sex and age. These causes are numerous, but they chiefly consist of external injuries of various kinds, more especially punctures, lacerations, abrasions, fractures, and contusions; punctures or divisions of veins, particularly with blunt, ragged, foul or poisoned instruments; wounds, punctures or injuries in anatomical dissections or during post-mortem inspections; cuts or scratches when preparing or dressing animal food, especially game, &c.; operations, &c., when performed in foul wards of hospitals, or in low, impure, and ill-ventilated localities or apartments;\* fractures, compound or comminuted, in similar circumstances; ligatures or surgical operations on veins; the application of caustics or local irritants; the existence of ulcerated or tubercular cavities, or of abscesses or malignant formations, with which veins communicate, or into which either of these morbid matters pass; and the inhibition of morbid matters by veins or sinuses, from cavities in which morbid secretions, fluids, or deposits accumulate, as the cavities of the uterus and cervix uteri, or from ulcerated cavities in the lungs, liver, &c., or from necrosed bones or splacelated structures, or from purulent matter lodged under the flaps formed in amputations.

[\* Inflammation of veins is more common after surgical operations than is generally supposed. We have known several fatal cases, not only from venæsection in the arm, but also ligature of varicose veins in the leg and the testicle, and where every precaution was used to guard against consecutive accidents. Such cases may be found in all our medical journals and works on surgery; in some cases the fatal inflammation has resulted from incision, in others from excision or ligature. Mr. TRAVERS and Sir ASTLEY COOPER have recorded several such instances. In regard to inflammation from phlebotomy, Mr. ABERNETHY imputes it to moving the arm soon after bleeding. Dr. THOMSON, of Edinburgh, ascribes it chiefly to the dullness of the lancet. Other good authorities believe that the latter is not sufficient to cause the disease, unless there be present a peculiar irritability of constitution. Much, however, must be owing to atmospheric conditions, as we find phlebitis far more common at some seasons than at others. This is true both as regards traumatic as well as other kinds of phlebitis. Punctured wounds, if the instrument be charged with some putrid or irritating matter, are very apt to produce inflammation of deep-seated veins; and instances have occurred where such a result has followed from using a lancet previously employed for vaccination, and not thoroughly cleaned.]

These last, venæsections, and punctured or other wounds, are the most common exciting causes of phlebitis.

12. In hospitals, especially during the prevalence of hospital gangrene or erysipelas, either within them or in their vicinity; in camps or barracks, prisons or crowded vessels, especially transports; and in low, damp, crowded, and imperfectly ventilated situations, and in localities exposed to noxious exhalations, particularly in malarious states of the air, or when erysipelas is prevalent in them, and when the more common exciting causes are of frequent occurrence, phlebitis may then assume an endemic or epidemic prevalence. In these circumstances and seasons, venæsection and other operations involving veins can seldom be performed without the risk of producing the asthenic, or most dangerous form of phlebitis (§ 21, *et seq.*); and, indeed, these operations, especially venæsection, should be on such occasions avoided as much as possible.

13. Phlebitis is sometimes not only *caused* by, but often also *associated* with, organic lesions of internal organs, especially with ulcerations of the intestines, with abscesses in the liver, kidneys, lungs, brain, ears, &c.; and is occasionally detected in the mesenteric, the portal, and the pulmonary veins, and even in the veins and sinuses within the cranium, upon dissection. It is, however, most frequently associated with uterine diseases, and with inflammations and abscesses of the uterine ligaments; the iliac, spermatic, and other veins, having become consecutively inflamed, as stated in the articles on diseases of the PUERPERAL STATES, and of the UTERUS.

14. ii. SYMPTOMS.—A. The *symptoms of sthenic phlebitis* may be divided into *two stages*, namely, 1st. Those which are local, and characterize the local limitation of the malady; 2d. Those which indicate the contamination of the blood, and general infection of the frame. 1st. *The local signs* are generally very manifest when any of the more superficial veins are attacked; but they are very equivocal when the deep-seated and internal veins are implicated. Phlebitis usually commences with sharp or severe, sometimes violent, pain in a part, or in the course, of a vein. If the vessel be superficial, it will be found hard, tense, as if stretched, forming under the skin a cylindrical or knotted cord. At the same time the skin sometimes presents a reddish line or more extensive erythematous blush, or even an erysipelatous appearance. If the vessel is more deeply seated, tension and hardness may be felt in the situation or course of the pain. Congestion or engorgement of the capillaries of the cellular tissue adjoining or surrounding the inflamed vein are afterward observed; and if several veins, or a large trunk is affected, this tissue, and the parts below or distal to the seat of disease, become œdematous, or very remarkably swollen. With the local lesion, the constitution sympathizes more or less remarkably, the general symptoms varying with the severity and extent of the inflammation, and with the temperament and habit of body of the patient; but quickness of pulse, heat of skin, headache, loss of appetite, thirst, and impaired secretion and excretion, with other symptoms of inflammatory fever, are commonly observed.

15. In favourable states of the constitution, and when judiciously and early treated, the disease may not proceed farther. The coagulum

formed in the inflamed veins adheres to the parietes of their canals; a collateral circulation is established, and the inflamed veins no longer permit the circulation of blood through them. In some cases the inflammatory exudation on the internal surface of the vessel, or the coagula formed on its sides by means of this exudation, leave a central canal, allowing a partial circulation of blood along it. In other instances the inflamed veins secrete pus, which may be so abundant as to give rise to fluctuation, or other indications of its presence in the sub-cutaneous cord, which is felt when the vein is superficial; and, if an artificial issue is not given to it, the matter makes its way into the adjoining cellular tissue, and forms an abscess, which follows the usual course. When the local lesion does not terminate in either of these ways; and when the morbid exudation, or purulent matter furnished by the inflamed vessel, is carried into the blood, the system becomes generally infected, owing to the contamination of the blood thus produced, and the second period or stage of the malady is developed—or the state of *pyæmia*.

16. 2d. This stage of phlebitis, or that of *vascular infection*, may take place rapidly, or not until after a few days, the rapidity of its occurrence depending upon the nature of the exciting cause and the constitution of the patient. It usually commences with chills or rigors, followed by hot skin and other symptoms of fever, and by perspiration. These paroxysms of chills, fever, and sweats generally return at irregular intervals, assuming a remitting form; but in some instances they are periodic. With these exacerbations, anxiety, distress, or slight or occasional wandering delirium appear; and these are followed by more continued delirium, which is generally low or muttering, rarely lively or excited. The tongue, previously furred, now becomes dry or encrusted, is trembling, or imperfectly protruded; the teeth and lips are fuliginous; the countenance is sunk, dusky or pale, and lurid, and the symptoms assume a typhoid or adynamic character. The pulse is small, very frequent, and soft. These phenomena are observed in nearly all the cases at this stage; and others are less constantly present, especially retchings and vomitings; diarrhœa, the stools being dark and very offensive, the urine turbid and fetid or ammoniacal, and the surface dark or dusky, or slightly jaundiced.

17. During this stage, and often at an early period of it, secondary abscesses form in some internal organ, with indications of oppression, tenderness, or distress, referred especially to the regions in which the affected organ is seated. In some cases the larger joints become extremely painful and swollen, from the formation of pus within their capsules. Purulent deposits, without any very manifest indication of pre-existing inflammation, sometimes form not only in the internal viscera, or in the joints, but also in the intramuscular tissues, and even in the brain, occasioning profound coma. If this stage continue even for a few days, extensive bed-sores and sphacelations occur in the situations on which the weight of the body chiefly rests; and, the sensibility of the urinary bladder being in great measure lost, the urine becomes ammoniacal, or the functions of the kidneys much impaired, contamination of the circulation is farther increased, and its consequences accelerated, death generally

ensuing with a celerity according to the extent and rapidity of these changes.

18. The *extension* of the inflammation is generally in the direction of the heart, or of the current of circulation; but a fatal result often takes place before the inflammation reaches the vena cava, or even the larger venous trunks, owing to contamination of the blood by the exudation, or purulent matter, from the inflamed parts. In some cases, however, the disease pursues a different course, and extends to the smaller ramifications. Mr. ABERNETHY met with a case of phlebitis after blood-letting at the bend of the arm, in which the veins were affected down to the hand. This more unusual course is very probably occasioned by the complete obstruction of the part of the vein first affected by a coagulum or exudation of lymph. It may also be partly the result of the state of constitutional power. It is not infrequent in puerperal phlebitis, the cause of which is chiefly the imbibition of sanious matters from the internal surface of the uterus, aided by shock and vital depression, and by the predisposition produced by an impure air.

19. iii. OF THE DIFFERENT PATHOLOGICAL CONDITIONS OBSERVED IN PHLEBITIS.—The several pathological states constituting the different varieties of inflammation of veins have not been sufficiently investigated and demonstrated by pathologists; and most writers have described two varieties only, namely, 1st, the *adhesive* or common; and, 2d, the *suppurative*; and, while they have viewed the former as merely a local disease, they have considered the latter as productive of vascular contamination and general infection.—a. Of these varieties it may, however, be remarked, that, although the *adhesive* is characterized chiefly by an exudation of lymph more or less adhesive and concrete, on the internal surface of the inflamed vein, and often no farther affecting the blood than causing the formation of a clot within or near the inflamed part, yet it is attended by more or less sympathetic febrile disturbance; and that the coagulum thus formed may be productive of much consecutive disease of the vein, if the local and constitutional treatment be not judiciously managed. Even after the exudation of lymph, or the formation of a coagulum, by means of which the extension of the inflammation and contamination of the blood are prevented, if constitutional power and vital resistance be much reduced, the coagulum thus formed may irritate the internal surface of the vessel, and either perpetuate or rekindle the inflammatory action.

20. b. The *suppurative* variety of phlebitis is generally productive of contamination of the blood and of most dangerous constitutional disease. Nevertheless, instances are occasionally observed in which the purulent matter at first formed, mingling with the blood in the vessel, causes its coagulation, and the coagulum thus formed arrests the circulation and the extension of the inflammation in the direction of the heart, and either allows the morbid action to subside, or favours the extension of it to the more external coats of the vessel and to the surrounding cellular tissue, occasioning abscesses in the course of the inflamed vein, and prolonging the disease. In these cases little or no contamination of the general mass of blood takes place, unless the constitutional powers and vital resistance to the extension of the local disease be much impaired,

either by the continuance and amount of the local lesion, or by an injudicious or a too lowering treatment.

[We find the law of symmetry prevailing in the present as in the other diseases; thus in the viscera, as well as in the superficial tissues, abscesses, resulting from phlebitis, are constantly met with at points most closely corresponding with one another on the two sides of the body.]

21. *c. Asthenic, or diffusive, or poisoned phlebitis*, has not hitherto been described as a very important variety, although it is the most dangerous of any form which the disease assumes. It occurs in all the circumstances, and arises from all the causes, which occasion the other forms of phlebitis. But it more especially proceeds from causes superadded to these, more especially from those which depress the vital energies and infect the system. It is generally the result of two classes of causes: 1st, those which depress the constitutional powers, and produce more or less of general cachexia before the vein is injured or wounded; and, 2d, those which lower or exhaust the energy of the body, and either prevent the depuration, or favour the contamination of the blood during or after the infliction of the injury or the other exciting causes of the phlebitis. The first class comprises malaria of all kinds; the foul air of crowded wards; or that produced from the discharges or exuviae of the sick or of others; improper or insufficient food, &c.; the second includes those already mentioned, when they come into operation during and after the infliction of the injury, or subsequently to the other exciting causes of the disease, violent shocks to the vitality of the frame, poisoned wounds, abrasions, &c., infectious emanations from erysipelatous or gangrenous sores, or morbid discharges; the absorption of purulent, putrid, sanious, or diseased matters from sphacelated, necrosed, or otherwise altered structures, or of decomposed blood, or vitiated secretions and excretions.

22. (*a*) This variety of phlebitis is characterized by the rapidity, severity, and the fatal tendency of the local and constitutional symptoms, and the marked depression of vital power, and the contamination of the circulating fluids, by which they are attended. Organic nervous energy is remarkably impaired, and all the manifestations of life more or less lowered. The functions of the brain are early disturbed, and the pulse becomes rapid, soft, open, and compressible; the surface of the body soon losing its vital appearance, and becoming livid, dusky, and sallow, sometimes dry and harsh, and ultimately clammy and cold. Delirium occurs early, and passes into stupor or coma. Locally, œdema, cellular infiltration, great tenderness on pressure, boggy swellings, and diminished temperature of the affected limb, are often remarked; and if the injured or affected vein be exposed, as when the disease follows venæsection in the circumstances just alluded to, the wound is gaping, union of the divided tissues not having taken place, and an ichorous or a sanious fluid exudes from the part, or slight hæmorrhage occurs on examination. In addition to the above more constant phenomena, others are observed, arising out of the varying combination of the predisposing and exciting causes, and the state of the patient. These are chiefly a tympanitic state of the abdomen, retchings or vomitings, diarrhoea, the evac-

uations being offensive and unnatural; the rapid occurrence of bed-sores; offensive or ammoniacal states of the urine, severe pains and swellings in the joints or extremities; congestions or puriform infiltrations of internal viscera, with tenderness and oppression referred to the regions corresponding with the affected organ, &c.

23. When *uterine phlebitis* takes place, it may assume either of the forms above described, and owing to such forms, and to the circumstances in which they severally appear, the different varieties of puerperal fever are developed; the more malignant kinds of these fevers being the results of the ichorous and sanious fluids imbibed from the interior of the uterus by the uterine sinuses and veins, or of the morbid exudation from the asthenically inflamed veins of the uterus and its appendages, and of the consequent contamination of the blood, aided by the vital shock of parturition, and by the foul or infectious air in crowded or ill-ventilated lying-in hospitals or wards. (See *art. PUERPERAL DISEASES*.)\*

24. *iv. The appearances* observed in dissection of fatal cases of phlebitis, as respects the *veins*, are described in the sequel (§ 57, *et seq.*); those which regard the frame generally are fully given under the head *PUERPERAL DISEASES* (§ 221, *et seq.*), and are nearly the same as those observed after *putro adynamic fever* (§ 513, *et seq.*); and those which are found when phlebitis occasions *consecutive and diffusive abscess* are described in the *art. ABSCESS* (§ 27, *et seq.*)†

[\* When the inflammation has been so violent as to occasion very decided changes of structure in the coats of the vein, the usual result is its complete obliteration. In consequence of this, extensive anastomoses often form, the activity of the vasa vasorum becomes conspicuous, and continues till the venous coats are reduced to a homogeneous lardaceous tissue. By their agency, also, the product of inflammation obstructing the vein is very gradually assimilated and absorbed. Meanwhile the walls of the vessel become more and more thickened, contracting in folds or wrinkles upon the narrowing canal, until at length the whole vessel is converted into a thin cellulofibrous cord. The obliteration of the fetal vessels is brought about by an analogous process, the only difference being that in this the process is purely a physiological one, there being simply a slender plug of coagulated blood to surmount, instead of the more heterogeneous products of inflammation. The obliteration of the vein is sometimes only partial, the plastic substance only blocking up part of the venous channel. The obliteration may be permanent, or only temporary, for a plug which closes up a large venous trunk will often be resolved and melted down in the sanguineous current, and that too without exciting any constitutional symptoms from absorption.]

† In the following case, by M. LE HERISSÉ, as quoted by Mr. ARNOT, some of the most remarkable secondary effects of phlebitis are described. "Gasper Goldinger, subject for the last six weeks to epilepsy, was bled twice from the arm on the 1st of November, 1846; on the 8th, from the foot; and on the 10th and 13th, from the jugular vein. On the 16th, he was again bled from the arm (the right), which on the following day felt painful; some redness and tension were observed round the aperture; 15th, arm very painful and swollen from the shoulder to below the elbow; edges of the puncture red; face and skin of the body of a yellowish colour, pulse feeble and frequent; 19th and 20th, fever more intense; tongue, dry and coated; great pain in the arm; 21st and 22d, lies supine; prostration of strength; heat of skin; tongue dry; pain in the right side of the chest; respiration short; 23d, tension of the arm diminished, some pus flowed from the wound made in bleeding; respiration short. I died at night, seven days after the receipt of the wound in the vein.

"*Dissection.*—The wound in the cephalic open; the vein filled with pus through the whole length, *i. e.*, from where it terminates in the axillary to the bend of the elbow, where it divides into the medial cephalic and superficial radial; the latter of which contained pus for two inches below its origin. The coats of the vein were much thickened, indurated, and red. In the interfibrillar cellular tissue of the pectoral muscle of the right side was

25. v. The DURATION of phlebitis is very variable. It is often very short in the asthenic and puerperal states, and may, when accelerated or exacerbated by the foul air in lying-in wards, not exceed 48 hours, although more frequently it continues several days, or even longer. Phlebitis consequent upon venæsection is rarely of less duration than three or four days. The suppurative form of the disease generally continues from ten to twenty-one days, and the adhesive form much longer, or several weeks; but the duration of each of the varieties of the disease varies much according to the causes, the treatment, and the constitution of the patient.

26. vi. SEATS OF PHLEBITIS.—Inflammation may attack several veins, or only one vein, or small part of a vein. It generally extends to the whole circumference of a vein, and is very rarely limited to one side of the vessel. The veins most frequently inflamed are those of the extremities, after wounds and injuries; next, those of the uterine organs and appendages, especially in the puerperal states, and the pulmonary veins. The veins least frequently affected are the ramifications of the portal and hepatic veins; the sinuses and veins of the dura mater; the vena cava, and the veins of the spine, and of the spongy structure of bones. Phlebitis of the umbilical cord, or inflammation of the umbilical vein in newborn infants, is not a rare occurrence. Several recent pathologists, more especially MM. RIBES and CRUVEILHIER, have supposed that the venous capillaries may be the seats of inflammation, and have ascribed erysipelas to phlebitis of the most minute of these vessels.

27. (a) *Inflammation of the veins of the arm* is most frequently consequent upon venæsection, and especially when this operation is repeated. It may, however, occur after amputations, fractures, punctured or other wounds, &c. It commences with pain in or near the seat of incision or puncture, extending upward. If adhesion has not taken place, the margins separate, swell, suppurate, and the pus formed in the vein escapes externally, especially if pressure be made on the vein from above downward. If the incision through the integuments has closed, the margins swell, and the cicatrix opens. The inflammation may extend from the seat of injury to the axilla, to the jugular, to the superior cava, or even to the right auricle. In this case death generally soon ensues, although instances of recovery have been recorded. The disease may also extend along the veins below the seat of injury, especially when the circulation in the vein is obstructed by lymph, coagula, &c. Phlebitis in this situation may present either of the forms described above.

28. (b) *The veins of the lower extremities, and the iliac veins*, or either separately, may be inflamed; the former from the same causes as occasion phlebitis in the arm, the latter most frequently as a consequence of the puerperal state, or of the cancer of the uterus, and of tubercular

disease. Inflammation of the iliac veins is most frequently manifested in the form of *phlegmasia alba dolens* (see this Art.), although phlebitis is not the only pathological lesion of this disease. M. TOULMOUCHE contends that the much more frequent occurrence of the malady in the left thigh than in the right is owing to the accumulation of feces in the sigmoid flexure of the colon, and to the consequent pressure made on the iliac vein, to the retardation of the circulation through it, and to coagulation of blood in it. (*Gaz. Méd.*, Avril, 1844.)

29. (c) *Inflammation of the vena porta* has been observed by MM. RIBES, BOUILLAUD, DANCE, and FREY, and they, as well as others, have ascribed redness of the internal surface of the ramifications of the vena porta, and of the hepatic veins, to inflammation; but it is not improbable that this appearance is more frequently owing to cadaveric imbibition of the colouring matter of the blood. True inflammation of the vena porta is a very rare occurrence; it is attended by a sense of weight and of pain in the right hypochondrium, greatly increased on pressure; by regular or irregular rigors; by extension of pain to the right shoulder; by jaundice, more or less developed; by nausea, vomitings, and sometimes singultus; by diarrhœa, more or less bilious, and ultimately by the usual indications of purulent infection of the blood. These symptoms are, however, in most respects the same as those accompanying acute abscess of the liver.

30. (d) *The sinuses of the dura mater* are not unfrequently inflamed, consecutively on injuries to the cranium, membranes, and substance of the brain, on inflammation of these parts, on inflammation of the ear, on caries of the temporal or other bones of the cranium. They may also become inflamed in the advanced course of erysipelas of the scalp, and of other maladies and lesions, as I have fully described many years since. (See art. BRAIN, Sect., *Inflammation of Sinuses of the Dura Mater, and of the Vessels of the Brain*, § 37, et seq., vol. i., p. 208, 9.)

31. (e) *The umbilical vein* has been found inflamed in recently born children, by MM. SASSE, BRESCHET, DUPLAY, TROUSSEAU, and others; and has been referred to ligature of the cord. It has been observed associated with erysipelas, with peritonitis, and with enteritis. The veins of bones have also been noticed by M. GERDY. *Uterine phlebitis* has been considered in the article on PUERPERAL DISEASES. (See § 189–197.)

32. (f) *Inflammation of the vena cava* is met with only consecutively upon inflammation of the uterine iliac or other veins. M. BÉRARD has found inflammation of the vena cava extending as high as the confluence of the renal veins in cases of *phlegmasia dolens*: cases of inflammation of the cava have been observed and described by TRAVERS, HODGSON, DANCE, and others. The symptoms indicating extension of inflammation and of its consequences to this vessel are rather inferential than positive. These consequences are the exudation of lymph, the formation of pus, or of coagula, or of all these, and more or less obstruction of the circulation along the vena cava. If there be observed consecutively upon phlebitis of either lower extremity acute or rapidly developed œdema, or dropsy of both the extremities, especially during the puerperal state, or at an advanced stage of fever, or at an early period after the subsidence of fever; and if, after the

a quantity of thick greenish pus. Eight or ten ounces of yellowish opaque serosity were contained in the right sac of the pleura. The lung of this side was unadherent, that of the left was adherent over its whole surface by a delicate false membrane. Both lungs presented a number of hepatized portions, varying in size from that of a nut to that of a large walnut, gorged with fluid, which in some of them was puriform. The arachnoid membrane was opaque, thickened, and indurated, effusion of fluid between it and the pia mater, and into the texture of the latter. Some yellowish serum in the ventricles."

occurrence of œdema of both extremities, indications of the development, in the surface of the trunk, of a supplemental venous circulation, it may be inferred with much probability that inflammation and its consequences have extended to the vena cava.

33. *Obliteration* has been observed by HALLER, WILSON, BAILLIE, CLINE, REYNAUD, the writers already named, and by others, to follow inflammation and obstruction of the vena cava. The cases which have been recorded of this remarkable lesion have presented extensive anastomoses, not only between deep-seated veins, but also between the principal superficial veins of the trunk, these latter appearing uncommonly enlarged, and anastomosing with each other. This very great development and free anastomoses of the superficial veins of the trunk have followed gradually upon the dropsical or œdematous state of both extremities; but in some cases, especially those under consideration, and of most marked enlargement and anastomoses of the superficial veins, the œdematous state of the lower extremities gradually diminishes. The particular veins by which the supplemental circulation is carried on are in some respects different in different cases, according to the seat of obstruction or obliteration of the cava, and to the trunks of veins, from which the inflammation extended.

34. vii. *THE DIAGNOSIS.*—Phlebitis may be mistaken, at an early period of its course, for lymphangitis, or the latter may be mistaken for the former. But the large cylindrical cords, wreathing in diverse forms, appearing when the superficial veins are inflamed, and the œdema of the distal or more remote parts, cannot be readily mistaken for the reddish, painful, small, straight, and knotted lines passing in the direction of, and enlarging, the lymphatic glands, above the seat of the complaint. In neuritis and neuralgia the pain is more acute or pungent than in phlebitis, and the appearances observed in phlebitis are not present, especially the œdema of the parts below the seat of pain, &c. When the consecutive or contaminating effects of phlebitis supervene, the low fever, the dusky, sallow, and discoloured skin, the diarrhœa, the rapid weak pulse, delirium, &c., although assuming the form of adynamic fever, may be distinguished from this latter by the antecedent local symptoms, by the causes, and by the whole history of the case.

35. viii. *THE PROGNOSIS.*—The danger of phlebitis is always considerable, because, although it is by no means imminent as long as the disease is merely local, yet infection and contamination of the blood, on which great danger depends, may unexpectedly and suddenly supervene. The symptoms described above (§ 16, *et seq.*) as indicating this contamination of the blood, and more especially those which attend consecutive or diffuse abscess in the lungs, liver, or other organs, are always those of extreme danger. Cases presenting signs of internal consecutive abscess are irremediable.

36. ix. *PATHOLOGICAL INFERENCES.*—(a) The liability to phlebitis as a consequence of the operation of any of the exciting causes, or even without any other cause than that which favours this liability, is great in proportion to the amount of hæmorrhage, or of vascular depletion, which has been the result of the injury or incision of a vein.—(b) Persons addicted to the abuse of intoxicating liquors or of tobacco are more liable to this

malady than others; and the liability extends to those who are weakened or anæmied by pre-existing disease, or who are of an unhealthy or cachectic habit of body.—(c) In the circumstances now stated, and in convalescents from, and even in the advanced stages of, exanthematous and adynamic fevers; in the course of acute rheumatism, of pulmonary consumption, and of diseases of the womb and its appendages, blood may coagulate in some situations in the veins, owing either to its remora, or to its altered state, or to defective vital power in such situations, and may inflame the inner coats of the vein in which it coagulates.—(d) The passage, or imbibition of purulent, ichorous, sanious, putrid, or tubercular matter into a vein or venous capillary may either coagulate the blood as it circulates onward in a venous trunk, and in consequence of this coagulation inflame the vein; or the morbid matter may irritate, inflame, or poison the internal surface of the vein, the inflammatory exudation from the inner coats of the vein coagulating the blood in it, or, failing in this, contaminating the blood circulating through it. It must be difficult to determine the exact sequence of results, and probably either or all may supervene.—(e) The morbid alterations in the veins may extend far along the veins from the seat of injury, as that produced by blood-letting, or even to the vena cava, or to the heart itself; and they may proceed also in an opposite direction, or beyond the injured part, although rarely to any considerable distance; the fatal issue, however, is not owing to this extension, although aided by it, but is chiefly the result of the contamination of the blood, and of the effects produced by this contamination on the organs and tissues of the frame.—(f) Consecutive diffuse abscess in the viscera, suppuration of joints, &c., are not occasioned by the transmission and deposition of purulent or other morbid matters from inflamed veins, or absorbed from primary seats of suppuration, caries, or other disease, but are the consequences of acute asthenic inflammations of those viscera or joints caused by the thus poisoned or contaminated blood.—(g) The sequence of morbid phenomena, or the succession of alterations from the commencement of irritation and inflammation in the vein until the disorganization consequent upon the diffusive suppurations ultimately produced in the viscera or joints, is accelerated by means which lower vital power and diminish the amount of blood circulating in the body.\*

37. II. *TREATMENT OF PHLEBITIS.*—The concluding one of the above inferences will indicate the principles which, in my opinion, should guide our practice in phlebitis. The following circumstance may have had some influence in directing my attention and influencing my views regarding this important subject. When in London for a short time, in August, 1815, I had occasion to converse with a well-known public man of that time, who informed me that he had been, about thirty-five years previously, a patient of JOHN

\* The above inferences formed the conclusion of a paper read before the Medical Society of London in 1823, and were arrived at after an observation of many cases of phlebitis in France and Germany during 1815 and 1816, and during 1819 and 1820, and after duly considering the treatment which was there generally adopted. These inferences, as well as the treatment which I have recommended in consonance with them, have always been given in my lectures on Practical Medicine, from 1824 until 1842, when I ceased to lecture.

HUNTER, he having suffered an attack of inflammation of the veins after venæsection, which had been twice repeated, to a large amount, for pneumonia; and that the inflammation supervened on the last blood-letting. But it was not only the occurrence of the phlebitis after the last depletion which made the impression on my mind, but chiefly the treatment which he informed me had been prescribed by JOHN HUNTER in his case. This consisted, as he stated, of preparations of bark conjoined with other medicines, and of a very liberal allowance of port-wine—upward of a bottle daily—until he recovered. This treatment was altogether so different from what was generally taught in lectures and surgical works, that I continued to reflect upon it, and to contrast it with the means of cure which I afterward saw adopted on the Continent and in this country for this disease, and which are still recommended in surgical and medical works. When it is considered that a very large proportion of the diseases of the puerperal state, and most of the fatal cases of amputation, proceed from inflammation of veins, and from the imbibition of purulent or sanious matters by the veins into the blood, inflaming the veins and contaminating the circulating fluids, or, in other words, producing effects to which the term *pyæmia* has recently been applied, but with little regard to pathological accuracy, the importance of determining the true intentions and principles of cure for this malady must be apparent. Upon what rational grounds can we advise, as very generally advised, large local and general depletions, and a strictly antiphlogistic regimen for a disease which is frequently a consequence of such depletion and regimen? Upon what therapeutical principles can means be recommended for the prevention or cure of phlebitis that tend to promote the imbibition, or absorption, and the circulation of morbid or poisonous fluids in the blood, to prevent the formation of a healthy lymph whereby the extension of the disease may be arrested, and to prostrate the vital resistance opposed by the constitution to the contamination, not only of the blood, but also of the soft solids?—and to the production of all these effects the means usually advised for phlebitis most certainly tend. With what rational intention are means prescribed to arrest the extension of inflammation of the veins and the contamination of the blood that actually and incontrovertibly favour both these results, and that have a more certain tendency to accelerate, if not to cause, a fatal issue than the natural course of the disease itself? The operation of the means of cure in this disease require to be studied and ascertained with as great care as should be devoted to the pathological changes and the consecutive alterations which constitute the nature, and occasion the imminent danger of the malady. An empirical treatment of phlebitis more frequently increases than diminishes the danger; and such empiricism, whether in phlebitis or in any other disease, being the result of ignorance, increases the number of fatal cases, and generates and perpetuates in the mind of the practitioner who is

thus imperfectly informed a skepticism in which he takes refuge, and under which he attempts to conceal his ignorance and to debase his vocation. The skeptic in medicine is ignorant not only of the nature and procession of morbid phenomena, but also of the operation of remedial agents. He is incapable of forming rational views, and is quite impotent as to their accomplishment. He therefore decries what he feels himself incapable of performing, and instead of relinquishing his efforts, he endeavours to impute his failures to the imperfections, if not to the total inefficacy of the science; and by continuing his practice, and by thereby perpetuating his want of success, he persists in furnishing evidence, not only of his own incompetency, but also of the insincerity of his professions; he at once admits that he practices a lie; that he professes to perform what he has no hopes of performing; that he may delude, but that he can not cure.\* But, leaving the medical skeptic to luxuriate in his practice and in his belief, and advising him to reconcile the former with the latter, if this be possible in any other way than by relinquishing the one in favour of the other, I proceed to consider those indications and means of treating phlebitis which extensive opportunities of observation disclosed; opportunities, however, in which I was then an observer only, not an actor, and which furnished more numerous proofs of a practice which ought to have been carefully avoided, than evidence of any resulting benefit.

33. i. A VIEW OF THE TREATMENT which has been advised for phlebitis may, not without some advantages, precede the consideration of the means which I have long believed to be the most appropriate to this malady. Former writers have generally advised very opposite means for the different stages of the disease, for the local affection, and for the general infection of the frame consequent upon it. Thus we find, in one of the ablest treatises on diseases of veins (in *Dict. de Méd.*, 2d ed.) which have recently appeared, it is recommended to have recourse to general blood-letting, to the application of leeches in great numbers, and more or less frequently repeated according to the strength of the patient; to emollient fomentations; to refrigerants; to the application of ice, or to cold effusion to the seat of in-

[\* These remarks of our author furnish a very satisfactory explanation of the abandonment of rational medicine by some practitioners, and their adoption of homœopathy, hydropathy, and other forms of empiricism. Their ignorance of the true principles of medical science, and consequent want of success in the treatment of disease, gradually renders them skeptical in regard to the efficacy of the science; and they fly to visionary systems which promise greater certainty, and require no industry, no grasp of mind, or extent of knowledge to comprehend or apply. They do not seem to understand the causes of their failure, and hence attribute to the imperfections of the science what is solely due to their own ignorance and folly. There is no profession, no study, which requires such high order of intellect, such well-balanced powers of mind, such rare judgment and nice discrimination, such close observation and unerring logic as medicine, and yet every man who finds himself incompetent to gain a living in any other calling feels fully competent, without preparatory training, preliminary study, or close application, to assume the responsibilities of a practitioner of the healing art; and our free republican institutions, in their jealousy of encroachment on individual rights or pursuits, give free license to every ignoramus to experiment on the lives and health of the public. When the true objects of government shall be better understood, homœopathy and other empirics will meet no greater toleration than those who, under a less respectable garb, take a still shorter cut to reach the pockets of the community.]

\* "Les premiers accidens inflammatoires que l'on observe sur le trajet d'une veine seront immédiatement combattus par les antiphlogistiques les plus énergiques: Saignées; applications de sangsues en grand nombre, et plus ou moins répétées, suivant la force des sujets, fomentations émollientes, tels sont les moyens qu'il convient de mettre d'abord en usage." (*Art. Veine, Inflammation*, in *Dict. de Méd.*, 2d ed.)

inflammation, in the first or local period of the disease; and, in order to second the effects of this rigidly antiphlogistic treatment, the application of large quantities of mercurial ointment, so as to rapidly affect the salivary glands.\*

39. M. PASQUIER and others have had recourse to the application of narcotics locally, in the form of the decoction of poppy-heads, containing the watery extract of opium, or to similar applications, placed along the course of the inflamed veins, and frequently renewed, so as to be always wet. M. BONNET, of Lyons, has had recourse to a very opposite treatment, viz., to the application of the actual cautery to the part where the vein is wounded, in order to prevent the absorption of pus from the inflamed vein. But the cases which he has adduced in support of his practice are too few and inconclusive to found upon them so novel a plan of cure.

40. The local treatment advised by JOHN HUNTER, and advocated by ABERNETHY, REIL, VELPEAU, and others, had for its object to prevent the extension of the inflammation towards the heart, by enabling the constitution to throw out coagulable lymph at the inflamed part, by means of which the blood might be coagulated or the vein obstructed. Compression of the vein above the seat of inflammation was likewise advised with this intention. These measures often were successful, but they often also failed. The remedies prescribed, however, with this view, were not always appropriate to the period of the disease, or to the constitution and habit of body of the patient, and were often resorted to at a too advanced stage, when the blood had already become contaminated, and when means calculated to neutralize or to counteract the contamination, and to depurate the blood, were required. M. BRESNET attacked this very rational indication, or method, of arresting the extension of the inflammation, by contending that it was most difficult to obtain an adhesive form of phlebitis by medical treatment. But the supporters of JOHN HUNTER'S doctrine had more extended views than the mere development of the adhesive form of the disease by enabling the constitution to throw out coagulable lymph. They knew, or at least hoped, that the lymph effused would favour the coagulation of blood in the inflamed veins, whereby the circulation in these veins would be entirely obstructed, and the extension of the inflammation, as well as the contamination of the blood, would be either delayed or prevented, as they also knew that the best means of limiting inflammation in any surface, more especially in that of circulating vessels, were those which supported or developed constitutional power and vital resistance to the impression of injurious agents.

41. If the views as to the treatment of the local stage or changes in phlebitis were thus diverse, those proposed for the second stage, or that of vascular infection and contamination, were no less so. The young pathologists of Paris in this matter displayed their accustomed ingenuity; but beyond this quality no farther praise can be awarded them. Some, relying upon the experiments of MM. LEURET and HAMONT, who stated that the injurious effects of pus injected into the veins of animals were delayed or prevented by repeated

blood-lettings, proposed this mode of evacuating the morbid matters contaminating the blood; but they failed in showing how these matters could be removed with the blood which was taken away, without leaving the same proportion in the blood which was left in the body. The fate of those who were thus treated may be readily predicated. Then was proposed the opposite system; namely, to engorge the patient with diluents, by means of which the poisonous materials may be diluted, their action rendered less injurious, and their elimination promoted by means of the skin and kidneys. M. Piorry, the apostle of this doctrine, in his memoir on "pyohémie," or pyæmia, adduced some evidence in its support. The due promotion of all the depurating functions, not only those now named, but also those of the intestines and liver, by suitable means, and by appropriate combinations, are important remedies for the second stage of this malady, but in most cases more even than these are required.

42. Some writers have supposed that the morbid materials which have passed into the blood may be neutralized by disinfectant or similar agents, such as the chlorides; and in certain forms they may be of service, and may with some reason be resorted to. But upon what rational grounds can repeated emetics, or antimonials, or mercurials be advised, unless upon the pure empiricism which is based on imputed but very doubtful success? Other writers have dreaded the prostration of vital power, and its consequences, in the second stage of phlebitis, and have had recourse to tonics, especially to the preparations of cinchona, to wine, and various restoratives. The propriety of the practice cannot be doubted, especially if adopted at a sufficiently early period, and if conjoined with means appropriate to existing pathological states and to the circumstances of individual cases.

43. ii. TREATMENT ADVISED BY THE AUTHOR.—A question, preliminary to entertaining the subject of treating phlebitis, suggests itself, namely, *Is there any plan by which the disease may be prevented?* Phlebitis is most frequently a consequence of amputations and similar operations, and of operations on the veins themselves. Of these latter venæsection is the most common efficient cause. From long and diversified observation, I am convinced that, when phlebitis follows venæsection, this operation ought not to have been performed, the states of the constitution and of the circulation actually not requiring it; and that this has more especially been the case when it has been repeated more than once, or when the vascular depletion has been carried too far. Most of the fatal cases of amputation result from phlebitis and its consequences. Now what are the circumstances which favour the occurrence of phlebitis after amputations? These are chiefly, 1st. The shock given to the constitution by the operation; 2d. The anæmied state of the system and the exhaustion of vital power in many cases at the time when the operation is performed; 3d. The collection of purulent matter under the flaps, and bathing the surface of the stump, and the mouths of divided veins; 4th. The state of the atmosphere in hospitals, wards, and places in which the operation is performed and the patient is confined; 5th. The treatment immediately after the operation; and, 6th. The means used to produce insensibility. Each of these requires a few remarks.

\* The late Prof. Physic advised the use of blisters over the vein affected, to prevent the extension of the inflammation; and the practice has been generally and very successfully adopted in this country.]

44. (a) The shock produced by the operation, especially when great or prolonged, is not only the result of reduced vital power, but also the cause of coagulation of blood in the veins and of the injurious action of the coagulated blood on the coats of the vein (see *art. SHOCK*). Hence the more severe and prolonged the shock the more likely are these effects to be produced.

45. (b) Many cases require amputation, under unfavourable circumstances, and in others it is so long delayed, owing to the fears of the patient, until these circumstances are developed. When the constitutional power and vital resistance of the patient to disease are reduced, and the blood altered by impaired depuration and imperfect sanguification—when organic nervous energy is depressed, and the blood diminished in quantity, in crasis, or in red globules, or impaired in quality—then a predisposition to phlebitis, when the veins are implicated in surgical operations, is thereby produced.

46. (c) The collection of purulent matter under the flaps, often favoured by the union of the integuments, acts most injuriously on the internal coats of the veins; and it may even be partially absorbed by the mouths of the veins in the surface of the stump, thereby producing pyæmia and its usual results. These effects are the more likely to occur in cases where vital power is greatly reduced, or where the quantity of the blood is much diminished and the quality much impaired, and where the patient breathes a close or contaminated atmosphere.

47. (d) The injurious influence of a foul air in cases where veins are implicated in surgical operations is sufficiently manifest; and the frequency of phlebitis and pyæmia in hospitals, both civil and military, from this cause, is often greater than is supposed. I witnessed this influence and its effects in numerous instances soon after the Peace of 1815, both in France and Germany; and in many more neither the cause nor the effect was recognised. The treatment also in these circumstances, and immediately after operations implicating veins, was often injurious and calculated to occasion the mischief which it was intended to prevent. At the period now alluded to, notwithstanding the writings of JOHN HUNTER, phlebitis and its consequences were but imperfectly understood. It was not until a few more years had elapsed that the pathology of the disease was fully investigated, and up to a very recent period, and even to the present time, neither the prevention nor the treatment of phlebitis has been satisfactorily illustrated. It has been a much too general practice to have recourse to a too strictly antiphlogistic treatment and regimen after amputations, thereby aiding other causes in producing phlebitis and pyæmia. The extent to which such treatment, however, should be carried, or how far its opposite should be adopted, as well as the means by which constitutional power may be promoted, and vital resistance to the invasion and extension of phlebitis be upheld, must depend upon the circumstances of individual cases and the acumen and experience of the physician.

48. (e) The means used to produce anæsthesia during surgical operations, not improbably may favour the occurrence of phlebitis and pyæmia. This topic requires careful examination. A recourse to those means has its advantages and disadvantages. The former are, the greater readi-

ness of the patient to submit to an operation at a time when it is most likely to be successful, and the feeling in the mind of the surgeon that he is not inflicting suffering. The latter are, the depressing influence of anæsthetics on vital power, the extinction of that amount of pain in operations, which, when not too long protracted, tends to develop a salutary reaction, and to favour the prevention of injurious changes after the operation; and, more especially, the alterations produced in the constitution of the blood by the passage of the anæsthetic vapour into it. These disadvantages were urged by me on several occasions immediately after the discovery of the means of producing complete anæsthesia, and subsequent observation has confirmed my opinion respecting them.\*

49. From the above it will be inferred that the avoidance, as far as may be, of the several circumstances which favour the production of phlebitis is of great importance; that all operations implicating veins should be performed in as healthy a state of the system as may be possible; that vital power and resistance should be supported, and not depressed; that all contaminating influences should be avoided; that the healthy constitution of the blood ought to be studied before and after such operations, and nothing done to alter it; and that the confidence of the patient in a successful result should be upheld, and roused or increased when depressed. Conformably with these propositions, it will be manifest that a pure, dry, and temperate atmosphere; perfect repose of a limb or a part in which a vein has been injured or wounded; protection of a wound in a vein from the access of the atmosphere; and a healthy discharge of the digestive and depurating functions, and physical and mental quietude, are among the most essential means of preventing phlebitis, and of counteracting or neutralizing many of its causes.

50. i. TREATMENT OF THE FIRST OR LOCAL PERIOD OF PHLEBITIS.—This should vary with the causes of the inflammation, with the symptoms complained of, with the habit of body of the patient, with the presumed extent to which the disease has advanced, and with the situation of the inflamed vein. The causes and seat of the inflammation equally forbid general depletion; and, unless in very plethoric or robust subjects, even local depletions are seldom required. Pain and tenderness are rarely removed by them, even in these subjects, and never in persons otherwise circumstanced. Fomentations, especially those usually applied, sometimes assuage the pain, but they favour the extension of the inflammation along the vein, and prevent or diminish the chance of procuring the occlusion of the vein by

\* The experience of surgeons in the United States does not coincide with that of Dr. COPLAND in regard to the influence of anæsthetics in favouring phlebitis. On the contrary, it is believed that the mortality from severe operations has been much diminished in consequence of their introduction and employment. The depression of the vital forces, as well as the changes produced in the blood through their influence, is but temporary; while the patient is wholly exempted from the violent effects of the shock, which of itself is far more dangerous and depressing to the vital powers than any of the anæsthetic agents. We have carefully watched the secondary effects of both chloroform and ether in every variety of subject, and under every mode of administration and quantity, and we have never yet seen an instance where we thought the reparative process was interfered with, or the cure retarded by their use. Theoretical considerations may possibly lead to such a conclusion, but it will not be confirmed by observation or experiment.]

the production of coagulable lymph in the inflamed part. The *chief objects*, as to the local affection, are, to diminish inflammation and its usual products in the part; to render these products as little injurious as possible by causing occlusion of the vein, and by these means to prevent the contamination of the blood and the superpervention of the second stage of the disease by the usual exudations which take place into an inflamed vein. The means which are most to be depended upon for the fulfilment of these intentions are generally those which also remove the more distressing local symptoms; and, while they thus act, they tend equally to promote the *three objects* now proposed. The local as well as the constitutional means may be varied to meet the exigencies of particular cases, and the circumstances just alluded to; but even while the disease is still local, internal remedies should be prescribed, as well as local applications. These latter have been, for the cases which have come under my care, since the commencement of my practice, either one or other of the *liniments* prescribed in the APPENDIX (see Form. 295, 296, 297, 300, 307, 311), applied in the form of an *embrocation* over the seat of the phlebitis, by means of two or three folds of flannel or of spongio-piline; or an epithem of spirits of turpentine, or the embrocation prescribed at p. 1257, of the third volume, applied in the way now stated, the access of air to the wounded vein being assiduously prevented.

51. While either of these embrocations is being applied, internal means should be prescribed with due reference to the state of vital power and vascular action, and to existing morbid sensibility and irritability. Care, however, should be had that the medicines prescribed are not such as may occasion vomiting or excessive action of the bowels, as either or both will promote the passage of the products of inflammation into the blood, or render these products more likely to pass into the circulation. The medicines prescribed internally during this period should have for their main objects to prevent the extension of inflammation along the veins, and to assuage pain and irritability: the former of these can be attained only by developing vital power and resistance; and the means best calculated to attain this end may be conjoined with those which affect the latter object. With these intentions I have not unfrequently prescribed the following, varying the individual substances with the varying circumstances of individual cases.

No. 367. R Quinæ Sulphatis; Ferri Sulphatis; Camphoræ, aa, gr. xij.; Pilulæ Galbani comp., ℥ij.; Extr. Opil, gr. vj. (vel Extr. Hyocyami, gr. xvij.); Pulv. Capsici, gr. xij.; Bals. Peruviani, q. s. M. Contunde bene et divide massam in Pilulas xxx., quarum binæ sumentur 4tis vel 6tis horis.

No. 368. R Ferri Sulphatis; Quinæ Sulphatis, aa, gr. xv.; Camphoræ, gr. xij.; Extr. Hyocyami, zss.; Extr. Aloë purif., gr. xij. (vel Pilulæ Aloë cum Myrrha, ℥j.); Pulv. Capsici, gr. xij.; Olei Cajuputi, q. s. Miscet et contunde bene. Divide massam in Pilulas xxx. Capiat æger ij. 4tis vel 6tis horis.

No. 369. R Liquoris Ammonie Acet., ℥j.; Spiritus Ætheris Nitrici, zss.; Ammonie Sesquicarbon., zss. (vel Spirit. Ammonie Aromat. 3jss.); Tinct. Cinchonæ comp., ʒvj.; Tinct. Serpentariæ, ʒijss.; Tinct. Capsici, zss.; Infusi Cascarillæ (vel Decocti Cinchonæ) ad ʒviij. Miscet. Cochlearia ij. vel iij. larga sumentur quartis vel sextis horis.

No. 370. R Olei Terebinthinæ, -ijss.; Spiritus Ætheris Sulphurici comp. (vel Ætheris Hydrochlorici), zss.; Tinct. Camphoræ comp., zss.; Olei Cajuputi, zss.; Pulv. Tragacanth. comp., ʒij.; Pulv. Glycyrrh., ℥ij.; Syrupi Rosæ et Syrupi Tolutani, aa, ʒij.; Infusi Cascarillæ (vel Infusi

Cinchonæ) ad ʒviij. Miscet. Capiat æger Cochlearia ij. vel iij. larga 4tis vel 6tis horis.

No. 371. R Potassæ Bicarbon., ʒij.; Ammonie Carbonatis, zss.; Tinct. Cinchonæ comp., ʒvj.; Tinct. Serpentariæ, ʒij.; Tinct. Capsici, zss. ad ʒj.; Infusi (vel Decocti) Cinchonæ ad ʒviij. Fiat mist. cuius cochlearia ij. vel iij. larga sumentur ter quaterve in die.

52. An apparently high or tumultuous vascular action, or an open, broad or even bounding state of the pulse, should not deter from a recourse to these or similar means; for these phenomena will much more readily subside under the influence of these than of those of an opposite nature; for vascular action is often the greatest and the most tumultuous when vital power is most deficient, especially when any part of the vascular system is inflamed. By developing and increasing vital power by suitable means, in these circumstances, we more readily overcome or appease morbidly increased vascular action. Although it is not desirable to produce much action on the bowels, still the depurating functions should neither be impaired nor arrested. Hence the remedies may be combined as in No. 368, in order to prevent this result; or equal parts of castor-oil and oil of turpentine may be taken on the surface of an aromatic water, or these substances, in larger quantity, may be administered in an enema.

53. During the local limitation or period of the disease the system sympathizes with the local morbid action, occasioning much febrile disorder, which, although the above means may not for some time either diminish or increase, will not pass into that adynamic condition which readily supervenes upon a lowering treatment of phlebitis, owing to the effects of such treatment upon the local morbid action and to the passage of the inflammatory products into the blood. If, however, notwithstanding the means, local and constitutional, now advised, the inflammation of the vein either extends, or produces a puriform fluid, or in cachectic habits of body an ichorous or sanious exudation, which readily passes into and commingles with, and contaminates the blood, the most strenuous efforts should be made to support vital power and resistance, to counteract or neutralize the injurious action of the contaminating materials, and to remove them from the circulation by means of the depurating organs.

54. In this, the *second or contaminating* period of the disease, the treatment will necessarily vary with the states of the several depurating functions—of those of the skin, bowels, and kidneys. The excretions from these must be frequently examined, and the means of cure prescribed appropriately to their several conditions. If the urine presents an acid reaction, the mixture No. 371, last advised, may be continued, with or without the addition of the chlorate of potass or nitrate of potass, or both. If the urine be neutral or alkaline, or contain the phosphates in excess, then the nitro-muriatic acids may be given instead of these and of the alkalies contained in that prescription. If the skin be dry, or parched, or hot, the mixture No. 369 will generally increase the cutaneous functions, especially if promoted by suitable diluents (§ 56). When it is manifest that neither the hepatic nor the intestinal functions are sufficiently discharged, then the pills already prescribed may be given; or pills containing a full dose of calomel and camphor may precede either them, or the castor-oil and turpentine draught and enema above recommended (§ 52).

If the bowels become inordinately relaxed, the tonics already mentioned or others may be conjoined with astringents, small and frequent doses of creasote, absorbents and antacids, and with tincture of opium, or with compound tincture of camphor; or with any of the several remedies advised for DIARRHŒA or DYSENTERY (*see those articles*), according to the features of the case. It should not, however, be overlooked that relaxation of the bowels is a mode of vascular depuration, especially when the hepatic functions are duly performed, and that this relaxation should not be arrested unless it increase, or reduce the patient; but be moderated only, constitutional power being duly supported by the means already prescribed, aided by suitable nourishment, and by a sufficient supply of wine, at regular intervals.

55. In these and similar cases evincing not only great depression of vital power, but also more or less deficiency in the quantity and quality of the blood, the quinine, or the decoction of cinchona, chalybeate preparations, and other restoratives, may be given in increased or more frequent doses; and wherever pain, oppression, or uneasiness may be manifested, the embrocations advised above should be applied and renewed from time to time. In these and analogous states the tonics will be advantageously conjoined with camphor, ammonia, aromatics, &c., and with opium in moderate doses.

56. The diet, regimen, and beverages prescribed for the patient ought to be restorative, and calculated to promote nervous power. Rich wines, brisk, bottled malt liquors, or bitter ales; soda-water or Seltzer-water with wine; the alkaline and chalybeate mineral waters; spruce-beer and weak tar-water; Carara or lime-water with warm milk, &c., are the beverages which will be found most beneficial. Free ventilation, and a warm, dry, and pure air, are also most important aids of medical treatment. In most respects the treatment of the second stage of phlebitis is the same as that which is most efficacious for consecutive abscesses (*see art. ABSCESS, § 62, et seq.*), for the effects of absorption of morbid matter from diseased organs and structures (*see ABSORPTION, § 15, et seq.*), for inflammation of the LYMPHATICS (*§ 17, et seq.*), and for the consequences of animal or food Poisons (*§ 427-456*).

## II. STRUCTURAL LESIONS OF VEINS.—CLASSIF.

### —IV. CLASS, III. ORDER (*Author in Preface.*)

57. *a.* Inflammation of veins occasions redness, or a reddish-brown or violet tint of their coats. But similar changes, usually however of a more uniform character, are often produced in these vessels after death, by the imbibition of the colouring matter of the blood. Indeed, this is the most frequent source of the different shades of colour observed in the veins, these shades varying with the state of the blood, and with the period after death at which the examination had been made. The redness proceeding from this source is much more frequently met with in the veins than in the arteries, evidently owing to the constant presence of blood in the former after death. This change, however, differs in pervading all the coats of the veins, whereas it is generally confined to the inner membrane of the arteries. Redness, therefore, unaccompanied with other changes, cannot be considered as a proof of disease.

57\*. The veins, like other parts of the body, present alterations arising from the secretion of coagulable lymph or albumen. This plastic and organizable matter, in which a number of morbid formations originate, is frequently found in the veins, either extended into membranes or accumulated in amorphous masses. It is always to be viewed, particularly when connected with redness or vascular injection, as a result of the inflammatory act. The experiments which M. GENDRIN instituted upon the veins, as well as upon the arteries, have illustrated this point.

58. *b.* Coagulated lymph is found, 1st, in the interior of the veins; 2d, between their coats; and, 3d, on their external surface. When this is considerable, or obliterates the canal of the vessel, it generally becomes partially organized, and is changed to cellular tissue, if the life of the patient continue for some time. When the lymph is secreted in smaller quantity, so as not to interrupt the circulation in the vessel, it generally presents the form of a firm albuminous layer, without any trace of organization; but in some instances, as pointed out by RIBES, GENDRIN, and ANDRAL, it forms a delicate membrane, and presents evident traces of organization, being traversed by minute vessels. The surface of the vessel opposed to those membranes is sometimes, most commonly in the more recent cases, of a deep red colour; but in other cases, particularly those of older date, it is perfectly colourless. The coagulated albumen thus formed in the interior of the vein may constitute small patches merely, or small circumscribed masses, or a complete continuous layer extending through the whole of one or several vessels. The polypous concretions described by REIL (*Fieberlehre*, bk. ii., p. 215-297) belong to the second of those varieties.

59. *c.* Purulent matter is frequently found in veins. M. ANDRAL states that coagulable lymph may gradually lose its physical characters, and be insensibly transformed into pus. That this may happen previously to the coagulation of the lymph, is possible; but we have no satisfactory proof of its occurrence, and least of all, after the coagulation of this fluid has taken place. Indeed, it must not be supposed that the purulent matter formed in the veins is generally, or even frequently, produced in this manner. When it is found in the veins, it evidently does not proceed from a transformation of the plastic matter already noticed, but from a modification of the morbid action of the extremities which secrete that matter, and from a change in the vital condition and cohesion of the internal membrane of the vessel; this membrane being somewhat softened, and frequently tumefied or thickened. When the purulent matter is formed from the vein itself, it is found, 1st, in the cavity of the vessel; 2d, infiltrated between its coats; and, 3d, surrounding.

60. The purulent matter formed in the interior of the veins is, however, more frequently conveyed there from some other part with the blood, than secreted by an inflamed vein. When detected in a vein, it is either pure, or mixed with the blood or with coagula. When pus is found connected with coagula, it has been, in some cases, external to them, and in others contained in them. This latter phenomenon has led to some speculation on the part of certain pathologists. M. ANDRAL believes that pus contained

within a coagulum has been formed there in consequence of some peculiar modification of the blood itself. But this is merely a supposition, and is opposed by the consideration that the blood-globule can hardly be changed to a pus-globule, either during or after the coagulation of the blood. It is much more probable that the pus, whether poured into the vessel from its inflamed internal surface, or conveyed from a distant part with the blood, but particularly when it proceeds from the former source, is first formed, the blood coagulating around it, owing to some obstruction to the circulation in the vessel, or to the effect produced by the morbid secretion on the fibrin of the blood favouring its coagulation.

61. The irritation and inflammation producing suppuration of veins arise from various causes. These are stated when treating of inflammation of these vessels (§ 6, *et seq.*), where I have shown that inflammation originating in a part of a vein may be propagated both toward the heart and in the course of the smaller branches. The connexion of redness, thickening, softening, &c., of the coats of veins, with the formation of purulent matter in them, has been fully illustrated by the researches of RIBES, DAVIS, VELPEAU, GENDRIN, LOUIS, ARNOTT, LEE, TONNELLÉ, and DANCE; and similar appearances have repeatedly come before me in the examination of fatal cases of puerperal diseases. But pus is often formed in the veins without any change of structure of their parietes, particularly in those veins which arise in parts in a state of suppuration. I have observed in several cases, in which the uterus of puerperal patients contained purulent matter either in its cavity or in its sinuses, the uterine veins, and some of the veins into which they run, nearly filled with this matter. Similar appearances have been noticed by DANCE, LOUIS, and others. ABERCROMBIE and TONNELLÉ have found pus in the sinuses of the dura mater, in cases of caries of the bones of the head, &c. Pus has often been found in the veins near diseased joints, suppurating fractures, and unhealthy stumps, by RIBES, VELPEAU, and others. BLANCHARD long ago found pus in the vena cava, in a case of abscess of the liver. M. GENDRIN found pus in the veins in the vicinity of ulcers in the intestines. M. ANDRAL has met with similar appearances. I have stated in the article DYSENTERY, that abscess of the liver sometimes complicating that disease not unfrequently proceeds from the absorption of pus from the ulcerated intestines into the veins, which, circulating into the vena porta, excites diffusive or asthenic inflammatory action, rapidly followed by the formation of purulent matter in the substance of the liver. This view is confirmed by the researches of M. RIBES, who has demonstrated that the villi of the intestines are principally composed of minute branches of veins. M. ANDRAL found, on the examination of a case of diseased intestines and liver, the vena porta and its branches lined with a false membrane. When purulent matter is formed in a part, and afterward conveyed into the veins, as in the instances now alluded to, their coats are in some cases apparently sound, and in others inflamed or softened, or their interior is lined with a false membrane, &c. In the latter cases, either the inflammatory action has extended itself to the veins from the part primarily diseased, or the morbid secretions which have passed into them have

irritated and inflamed their internal membrane, at the same time that they have induced serious changes in the blood and system generally.

62. In asthenic or cachectic states of phlebitis, or when the cause is of a poisonous or septic character, the exudation from the interior of the inflamed vein is neither plastic nor purulent, and is so entirely of an ichorous and liquid nature as to mingle readily with the current of the circulation, and to rapidly contaminate and poison the blood and the soft tissues, and to destroy life. In such cases discolouring of the inner surface, and softening and thickening of the coats of the vessel affected, with an altered appearance of the blood—a dark, semi-coagulated or uncoagulated condition of this fluid. In these cases the blood is rarely, or if at all, coagulated, or very imperfectly coagulated in the diseased vein or veins, there is no plastic exudation on the internal surface, and no trace of pus in the vessel. The injurious operation of this ichorous exudation is accelerated by the circumstance of its failing to produce coagulation of blood in the vein; for when the exudation is plastic or purulent a coagulum is generally formed by these latter exudations; and this coagulum often prevents the extension of the inflammation and contamination of the blood and its consequences, while the ichorous and more liquid exudation hastens both these most dangerous or fatal results.

62\*. Thus the morbid states of veins may originate either in themselves or in the parts in which the veins commence; but, whether they be thus primary or consecutive affections, they exercise a powerful influence on the system, and on distinct organs, both through the medium of the blood and by continuity of tissue. 1st. Purulent matter secreted from an inflamed vein, or conveyed into the veins from an adjoining part, may mix with the blood, occasion febrile symptoms of an adynamic character, generally with colligative perspirations or diarrhoea, and be thus eliminated from the circulation nearly as fast as it passes into it, by the several emunctories. 2d. This matter, when once carried into the circulation, may be secreted from it into the parenchyma of some organ, the cavity of some joint, or even into cellular or muscular parts. 3d. Purulent matter circulating in the vessels, whether the pus-globules be metamorphosed or no, during their circulation, may induce inflammatory irritation, or such a state of the capillaries of an organ or part previously disposed to disease, as will be rapidly followed by the formation of purulent matter in such part, or by disorganization. 4th. Inflammatory irritation excited in the internal membrane of a vein, more especially in the asthenic forms, may extend in every direction to other veins, especially in that of the heart, and thus implicate other organs or parts. This diffusive form of phlebitis generally occurs in debilitated or unhealthy states of the frame, or when the disease is consecutive on other maladies, or caused by septic or poisonous agents. 5th. Inflammatory disease of the internal surface of the veins will give rise to a secretion varying with the state of the vital powers of the system, and this secretion carried along, and mixing with, the circulating current, will remarkably influence those powers, and depress or otherwise modify them. 6th. Inflammation attacking all the coats of a vein is more likely to occur in a healthy body than that confined to the inner surface, and is more com-

monly productive of an effusion of coagulable lymph, which tends to limit the inflammation, to prevent the admixture of the products of inflammation with the blood, and thus to preserve the blood from contamination. 7th. This sthenic form of inflammation most frequently occasions obstruction and obliteration of veins; and, if the obliteration be seated in large veins, serious local and general effects may result, owing to the mechanical obstacle thereby presented to the circulation.

[Analogy justifies the assumption that pus is secreted by the coats of the veins. VOGEL has fully demonstrated the transition of epithelium cells into pus-globules. SCHWANN having originally shown that all organic bodies are developed out of nucleated cells, HENLE followed up the observation, and proved that from these primary cells either normal or pathological forms may spring: consequently, inflammation would give rise to pus-globules. To apply these views to the formation of purulent matter within the veins: the cells of the epithelium lining separate from the internal membrane of the vein, so as to give a dull appearance to the inner surface of the vessel, and render it more susceptible of a morbid tinge from imbibition. The passing blood-corpuscles next assume a spheroid, or a gibbous appearance, advance with a slow revolving movement, or cling to one another, parting with their serum and with their pigment. The lining membrane of the vessel generates new, imperfect epithelium cells which mingle with the altered blood, and, finally, actual pus-globules, which, when congregated in sufficient number, completely arrest the current of blood, and affect the blood-corpuscles in the manner above mentioned. The simultaneous effusion of both fibrin and albumen now serves to complete the formation of a plug, which differs in its external character according to its more or less rapid development, and to the varying proportion of its constituent parts. Supposing suppurative phlebitis has now commenced, or is commencing, the plug, thus formed, grows softer towards its centre; it assumes a grayish, yellowish-white, dotted appearance, and finally exhibits a straw colour, and a semi-fluid consistency. Its laminated structure becomes more and more indistinct, and it is finally resolved into pus, which is usually confined within a fibrinous layer more or less thin, and rarely found loose within the vein. But the contents of the veins being unceasingly propelled towards the heart, the more or less solid products of inflammation are necessarily conveyed beyond the original site of inflammation. For this reason it would be premature were we at once to conclude, in examining a body, that the part of a vein at which we might happen to find a pus-coagulum must be the true seat of the disease. That seat is frequently remote, and difficult to discover: thus between a purulent coagulum in the inferior vena cava, and a gangrenous spot or a varicose ulcer on the leg, the whole extent of the iliac and crural veins, together with their deep-seated branches, shall be found perfectly healthy, while one or more branches of the saphena vein above bear all the evidence of intense inflammation. But *si nec pus*, by mingling with the blood, causes its coagulation, a decided hinderance is thereby offered, in the majority of instances, to the product of inflammation passing along with the venous current. The pus becomes isolated by the coagulation of blood both above

and below the place of its formation, and is thus cut off from the remainder of the blood. This has been called by some pathologists the *sequestration* of veins. Under such circumstances, the pus may be gradually removed by the process of absorption, the vein in the mean time becoming obliterated; or it may make for itself an outlet through the parietes of the vein. Then abscesses, varying in size and number, according to the amount of inflammation, form beneath the skin, or between the muscles, and the patient is thus protected against the dangerous consequences of a general infection of the circulating fluid. Is not such the origin frequently of the cold, deep-seated abscesses so often met with after injuries, and in vitiated constitutions? When pus has thus formed within an inflamed vein, its coats begin to undergo a change; their colour inclines to a grayish white; they become softened and thickened; and can no longer be distinguished from each other, forming with the surrounding textures a nearly uniform membranous layer of a lardaceous character and aspect. Soon after, a turbid, puriform fluid is often found deposited at intervals in the cellular tissue; in some instances, where the suppuration is active in the vicinity of the vein, the latter traverses the purulent channel for a considerable space, denuded in its entire circumference. Here the membranes of the vein gradually soften, and at length melt down, until no farther vestige of their texture is discernible within the common centre of suppuration.

If this process of *sequestration* does not take place, or but imperfectly, and the pus, or softened fibrin, passes at once into the general circulation, then all those phenomena ensue described by our author, the disease perhaps first assuming the type of an irregular intermittent, and subsequently of a typhoid or putrid and malignant character.

The morbid condition of the blood hence resulting leads to organic changes in every part of the body; all being referrible to stagnation of the circulating fluid, and are divisible into such as occasion a stagnation and interruption of the sanguineous current in the central portions of the vascular system, and into such as have their seat in the capillary system.

According to HASSE, the first series of changes consist in the formation of pus, and in coagulation of blood within the large venous or arterial trunks—even in the heart itself. The product of inflammation, whether pus or fibrin, follows the course of the blood towards the heart, but, advancing more slowly than the uncontaminated blood, accumulates, invests itself again and again with fresh layers of coagulum, and ends by entirely closing up the cavities of individual vascular trunks, and especially where a large quantity of blood has to pass within a brief space of time, and in which, therefore, the pus-globules and the fibrinous particles accumulate the more rapidly.

The pulmonary artery and its branches are most frequently the seat of this coagulation of the blood consequent on phlebitis, the plug which forms here perfectly resembling that of the adhesive inflammation of vessels. It is of a pale-brown colour, with here and there a yellowish spot, composed of concentric layers, and attached more or less closely to the walls of the vessel. These concrete masses, which have been observed in uterine phlebitis, and phlebitis consequent on uterine carcinoma, spread to the minutest extremities of the pulmonary artery, generally of one side only, and

causing death as soon, at least, as the main trunk becomes obstructed. In other cases similar coagulation occurs in the right cavities of the heart, in the form of *polypi* of the heart, as they have been called; which are of a grayish or pale violet colour, and having a stratiform and fibrinous structure. Internally they are sometimes found considerably softened, and occasionally containing liquid pus, while externally they are attached to the columnæ carneæ, and the valves of the heart. HASSE thinks that in order to produce such coagulation, it is indispensable, not only that a certain amount of morbid matter should pass into the circulating mass, but likewise that there should exist a peculiar predisposition of the body generally.

The most important pathological result of phlebitis, however, is that which involves secondary organic changes in the capillary system, called by some pathologists "*lobular inflammations*" and "*lobular abscesses*." They occur most frequently in organs through which the greatest portion of the blood is propelled within a short space of time, viz., the *lungs* and *liver*. They seldom occur in the spleen, kidneys, external skin, or cellular tissue; more rarely still in the brain, eye, and muscles. Serous membranes are not often the seat of this puriform effusion, the synovial membranes and pleura rather more so than the others. *Puerperal peritonitis* forms an important exception, though frequently the result of concurrent metritis. Veins, also, distant from those originally diseased, appear to be obnoxious to this secondary suppuration. The above explanation applies to abscesses in the liver and other organs, consequent on injuries of the head and other parts, which for so long a time were a source of mystery to medical men. These phenomena, then, are due to a phlebitis, in which the pus formed is not isolated, but mingles with the general sanguineous mass. As to the absorption of unaltered pus through the capillaries, it is hardly admissible on physical grounds. With regard to the abscesses that form in the lungs, liver, and spleen, it is now agreed by the best pathologists that these collections are not at once purulent at the outset, but the blood stagnates at certain points, producing suppurative inflammation of the surrounding tissue; or knots form of from the size of a pea to that of a walnut, become infiltrated with firm coagulated blood, and eventually suppurate. Formerly it was supposed that the pus formed within the veins at the part originally inflamed was transmitted through the current of the circulation to the lungs, liver, &c., and thus formed the abscesses in question. If pus be injected into the veins of horses, lobular abscesses will shortly afterward be found in the lungs. The pus-globules having reached the capillaries of the lungs, are unable, from their size, to permeate them, thus becoming central points of stagnation, and finally of extravasation in the minute branches of the pulmonary artery, and inducing inflammation and suppuration. VOGEL, however, considers it not impossible for single pus-globules to pass through the capillaries of the lungs, and HASSE remarks that it may be assumed that in some cases the substances commingling with the blood pass through the capillary system of the lungs without inducing any change in the pulmonary parenchyma. Some such admission seems necessary to explain the origin of purulent collections in other organs than the lungs and liver. Perhaps, as HASSE suggests, the nuclei of rup-

tured pus-globules may pass through the capillaries of the lungs into the general circulation, as also fibrin altered by the inflammatory process into finely-divided particles.]

63. *d. Softening* of the inner membrane of veins is often observed, and is generally conjoined with redness when it is the result of inflammation. Sometimes the softening is so great that the inner surface of the vessel is readily reduced to a pulpy state by gently scraping it with the back of the scalpel.

64. *e. Thickening* of this membrane is often associated with the foregoing changes; it may be either partial or general. In the former case the inner surface of the vessel presents an uneven appearance. But softening and thickening of the inner membrane of the veins are not always connected with redness; this membrane may present either of those alterations, or both of them, accompanied with paleness or with different shades of colour.

65. *f. The valves* of the veins are subject to the same alterations as the inner membrane. They are often deprived of their transparency, thickened, or partially destroyed; presenting the appearance of irregular fringes crossing the cavity of the vessel, and having generally coagulated blood adhering to them.

66. *g. The middle coat* of veins is often softened, generally at the same time as the inner. When this is the case, the vessel is torn with great ease. This coat is also subject to *atrophy*. When this exists the vessel presents an extraordinary degree of tenuity. *Hypertrophy* of the middle coat has been minutely described by M. ANDRAL. When this change exists, the coat is more distinctly visible, and its longitudinal fibres more evident. When the hypertrophy is considerable, this coat loses its transparency, acquires a yellowish colour, and becomes, to a certain degree, elastic, so that, when cut across, the vein remains open as an artery, to which it closely approaches in appearance. On minute dissection, however, the middle hypertrophied coat never presents any trace of circular fibres, nor does it possess the same degree of elasticity as the middle coat of arteries. M. ANDRAL states that he once detected, as he believes, muscular fibres in the vena cava inferior, near the heart; the cava was greatly hypertrophied. The hypertrophy in this case developed a structure similar to the natural condition of the vessel in some of the lower animals. In the horse, the structure of the vena cava near the right auricle is evidently muscular.

67. The middle coat, however, may be much thickened without actual hypertrophy or development of its fibres. This may arise from a deposition of fibrinous lymph in its texture, which becomes solidified by the absorption of its serous portion. M. ANDRAL accounts for this change by supposing that a quantity of blood accumulates in its tissue; that the colouring particles are absorbed, and the white fibrin remains behind in a solid form, combined, molecule to molecule, with the coats of the vein, presenting the lardaceous appearance described by authors as a particular tissue; but instead of having recourse to this complex explanation, would it not be preferable to consider this alteration as a result of chronic inflammatory action in the coats of the vein?

68. *h. The external coat* of the veins is subject

to the same changes as have been observed in the external coat of ARTERIES, and which are described in that article (§ 44). These alterations of both the middle and external coats are commonly seen after chronic phlebitis.

69. *i. Ulceration and perforation of the several coats of the veins are sometimes met with.* M. ANDRAL thinks that the latter is more frequently observed than the former. Perforation has been detected in the superior cava, both within and without the pericardium; in the inferior cava; in the vena portæ, both within and without the liver; in the splenic vein; in the jugular; in the subclavianæ; in the mesenteric veins, and in the veins of the extremities. The perforation is sometimes seen without any appearance of disease in the vicinity of the coats of the vessel, rupture taking place from external violence or muscular exertion. This form of perforation, or rather *rupture*, is most frequently observed in the vena cava and veins of the internal viscera. Instances of rupture of large veins are numerous. SCHENCK, MORGAGNI, DE HAEN, DOUBLEDAY, GROQUIER, LOVADINA, &c., have recorded rupture of the vena cava. MORGAGNI also found the pulmonary vein ruptured. In the majority of these and other instances, the rupture was occasioned by exertion or external injury. It is probable, however, that the walls of the ruptured vessel had been previously diseased. In cases of perforation the vessel is commonly more or less inflamed, ulcerated, softened, atrophied, &c.; and here, as well as in the case of rupture from exertion or violence, the perforation occurs from within outward; but the perforation may also proceed in a different direction; viz., from without inward, as when the vein is seated in diseased parts, as in carcinomatous ulcers of the stomach, or is pressed upon by a tumour.

70. *k. The calibre of veins may be much altered—may be increased or diminished—especially when the coats are diseased as described, the change of diameter occurring in the parts of their parietes which are affected.—(a) Dilated or varicose veins present a variety of appearances:* 1st. The veins may be simply dilated, in respect either of a whole vein or of portions of it, without any affection of the capillaries which nourish it, but more frequently with chronic inflammation of its coats; most probably the dilatation is the consequence of inflammatory action, this state disappearing, but the dilatation continuing. 2d. They may be dilated, either uniformly or at intervals, with thinning of their parietes. 3d. They may be dilated and their coats thickened, either uniformly or at intervals, the vessel being generally also lengthened, and consequently tortuous. 4th. They may be dilated and divided into compartments by the interposition of septa or partitions, between which the blood stagnates or even coagulates. 5th. They may be dilated, divided into compartments, and the dilated portions perforated, so as to allow the blood to pass into the cellular tissue surrounding the vein. M. ANDRAL thinks that the tumours described by the name of *erectile* are in reality nothing more than a cluster of small veins communicating with one another and with the surrounding cellular tissue by the perforations situated as now described.

71. The structure of every variety of hæmorrhoidal tumour may be referred to one or other of the foregoing varieties of dilatation or varix;

but these lesions are not confined to the veins in the vicinity of the anus. M. ANDRAL once found the external jugular altered in the manner described in the last variety. In some cases the tumours occasioned by dilated veins disappear spontaneously. When this occurs, the veins are generally obliterated. Some of the above kinds of varix, according to this pathologist, depend upon increased activity, others upon diminished activity of the nutritive process. Such, however, can be rarely the case. They are generally the results of pressure on the venous trunks into which the varicose veins pour their blood, or of some other obstruction to the circulation through the former vessel. In this case the varicose veins are not only greatly dilated and elongated, but their parietes are also hypertrophied.

72. *(b) Contraction and obliteration are, according to M. ANDRAL, much more common than their dilatation.* These lesions are occasioned, 1st, by obstruction in the interior of the veins; 2d, by causes seated in their parietes; and 3d, by mechanical compression external to them, generally from tumours, &c. The most frequent cause of the obliteration of the canals of veins is the spontaneous coagulation of the blood within the veins. That the blood may coagulate, during the life of the patient, within a vein or portion of a vein, and even within the sinuses of the dura mater, has been proved by the researches of many pathologists, particularly by MECKEL, GENDRIN, BOUILLAUD, RIBES, ANDRAL, CRUVEILHIER, ARNOTT, REYNAUD, ROKITSANSKY, myself, and others. It has occurred in several which have come before me in practice, especially in the advanced stages of low fevers, of acute rheumatism, of puerperal disease, and in dysentery. It is often difficult to assign the particular cause of the coagulation. It is, in some cases, apparently owing to the low state of the vital energies and their effect on the blood. In other cases it is probably occasioned by the morbid state of the valves already noticed (§ 65), or to lesion of the internal parietes of the vessel. Most frequently, however, it proceeds from coagulable lymph or pus secreted from the internal surface of the vessel; this morbid secretion adhering to the inflamed surface producing it, entangling the fibrinous and colouring parts of the blood, and thus forming a coagulum which either partially or entirely obstructs the canal. This coagulum generally varies in colour, density, and firmness of adhesion to the sides of the vessel; and it increases in bulk until the passage is entirely obstructed by it. Occasionally the coagulum becomes, in some respects, organized. Some of the pathologists whose names I have just adduced suppose that these coagula live precisely as the veins in which they are formed, and, like every other part endowed with life, keep up a constant process of nutrition and secretion, and are also liable to become diseased.

73. The canal of a vein may be altogether obliterated, and the vessel reduced to a fibro-cellular cord. This seems to be effected in a similar way to that observed in arteries. Obliteration of large venous trunks gives rise, as observed in arteries, to a collateral circulation, kept up by means either of small veins, or of one vessel that has acquired an unusual size. The most remarkable instance of obliteration was observed by M. REYNAUD in the superior vena cava. The veins on the lateral surface of the chest were remarkably enlarged, and anastomosed freely with the

epigastric veins, which were also greatly enlarged. The circulation was carried on chiefly by the vena azygos and inferior cava. The consequences of obstruction and obliteration of veins, especially œdema and dropsy, are well known. Several instructive cases of obliteration of the cavity of the vena cava, of the iliac veins, and of the sinuses of the dura mater, are recorded by BARTHOLINUS, RHODIUS, MANTISSA, BONTIUS, ALBINUS, HALLER, MORGAGNI, HODGSON, BRESCHET, WILSON, TONNELLÉ, REYNAUD, ANDRAL, and ROKITSKY.

74. *l. Ossific or calcareous* formations are rarely met with in the coats of the veins. They have, however, been observed by MORGAGNI, WALTER, MURRAY, BAILLIE, and TILORIER, and more recently by MACARTNEY, BECLARD, and ANDRAL, in the femoral and saphena veins. Sometimes these concretions protrude into the cavity of the vessel, either bursting its internal membrane, or carrying this membrane before them. In either case they may at last escape into the cavity and lodge there, without any attachment to the sides of the vessel; for in the latter case the membrane may contract behind the concretion, forming at first a peduncle attaching it to the vessel, which at last is ruptured or absorbed.

75. These concretions have received the name of *Phlebotomes*; they vary from the size of a millet-seed to that of a pea. They have sometimes been found in the centres of coagula, which had evidently been formed around them. They have been observed by COLUMBUS, WALTER, SOEMMERING, JOHN, and LANGSTAFF. F. TIEDEMANN has described them minutely. Those which he has observed, as well as those noticed by the pathologists just now named, were formed in the uterine and hæmorrhoidal veins. TIEDEMANN and ROKITSKY state that they are formed of concentric layers of the phosphate and carbonate of lime, sometimes with magnesia, united by albuminous matter, around a minute clot or coagulum; and deny that they are formed in the way which I have just stated (§ 74); and contend that they have been produced by a sort of crystallization, or deposition, of the earthy particles contained in the blood, around a nucleus which had formed in the nearly stagnant blood in the veins. M. ANDRAL also considers it possible that they may have been formed in the blood itself. It is difficult to assign limits to the range of possibilities without relation to the faith of those for whose belief they are adduced; but the question is, whether or no these concretions have ever been actually ascertained to have been formed in this manner. I believe that no such fact has ever been adduced.\*

\* The mode of formation of these concretions, or *vein-stones* as they have been termed, is for the most part as follows: Slow inflammation occurs in pouches or dilated portions of vein, and in the prolongations of small venous twigs, suddenly dilated, which results in conglutination of the blood in distinct concentric layers. These coagula, which are mostly spherical in shape, become the nidus for the deposition of phosphate of lime and magnesia, until at length the whole clot is transformed into a *phlebotome* or ossific mass, made up of concentric layers. When the dilated portion of the vein or pouch is thus filled up, its walls commonly become atrophied; the inner surface of the vein assumes more of a cellular structure, and closes firmly around the vein-stone, sometimes making it appear to be external to the vein. At other times the conglutination of the blood extends beyond the point where a vein-stone has formed, the calibre of the vessel closes up, and an entire portion of the implicated vein is obliterated. In other cases there is good reason to believe that they occur free and movable within vessels which continue

76. *m. Fatty, suety, and atheromatous deposits* have been found in the parietes of veins, but not nearly so frequently as in the coats of *arteries*, where I have first described them (§ 59, 60). BONTIUS states that he has met with large masses of fat in the vena cava, obstructing its canal. I have sometimes found fatty and suety deposits between the coats of the vena portæ; and M. ANDRAL has noticed similar deposits in this vein.

77. *n. Tuberculosis* does not occur either in or on the coats of the veins. If any tubercular matter, or substance resembling this matter, be found within the veins, it can proceed only from imbibition or absorption. But before this matter can be imbibed it must be softened, or metamorphosed, and thus have lost the tubercular characters.

78. *o. Cancer* is met with in veins in two ways: 1st. The walls of a vein may be attacked by a cancerous or carcinomatous growth, penetrated by, involved in, and closed or altered by this growth. The portal, renal, hepatic, and other veins may be thus implicated: 2d. The cancerous matter, especially when existing in other parts of the body, may constitute in a large vein a variously-formed mass, attached to the interior of the vessel, that may either partially or entirely fill and obstruct the canal. This cancerous formation obviously arises from the imbibition or absorption of the cancerous matter or cells into the veins, where they attach themselves and collect into masses of various sizes and forms. The œdema and swellings occurring in the last stages of carcinoma are, in some cases, attributable to this formation in the veins, and in others to phlebitis, produced by the imbibition of the cancerous matters.

79. *p. Gaseous fluids* have occasionally been remarked in the veins. In some cases they have proceeded from incipient putrefaction, but in others this could not have been the case. The vapours and gaseous exhalations from blood very recently taken, or at the time of its being taken from veins, and those found in veins after death, have not been sufficiently examined. They manifestly are such as demand a much stricter investigation than they have hitherto received. In cases of surgical operations, when large veins are divided, air not infrequently enters the veins; and if it rush in suddenly, and in considerable quantity, it is soon followed by death. The experiments of MM. MAGENDIE and PIEDAGNAL have demonstrated this fact conformably with what has occurred during several operations; but the mode in which this result takes place is not so evident. The air seems to act in deranging and arresting the contractions of the heart, and affecting the actions of the lungs.

80. *q. Entozoa* have been often found in the veins of the lower animals. The strongylus and filaria have been detected in the horse. M. ANDRAL found individuals of the class Nematodea in the vessels of a porpoise. In one only case he found Acciphalocysts (hydatids) in the pulmonary veins.

BIBLIOG. and REFER.—*Areteus*, Cur. Morb. Acut., 1.

pervious to the current of the circulation. Some pathologists maintain that they form in peculiar sacs in the cellular tissue, external to the vein; others think they are deposited between the coats of the vein, and ultimately get into the interior of the vein by absorption; while OTTO, TIEDEMANN, LORSTEIN, (RUEHLER, FRIQUET, CARSWELL, and LASSÉ suppose that they form originally within the vein, in the manner above indicated.]

Chapman*, Cases of Phlebitis, with some remarks on its Pathology and Treatment. (In this article Dr. C. gives several cases of Phlebitis from diss. treated successfully by leeches, fomentations, poultices, and blisters to the part, and calomel, ipecacuanha, and opium internally. "Of all remedies," he remarks, "the one deserving of the greatest confidence is a blister. Numerous are the instances in which I have witnessed its superior efficacy; and I believe there is little division of sentiment as to its extraordinary value among the profession in this part of the country. From what I have seen and heard, I cannot entertain a doubt that it will at once arrest a large majority of cases. But though coming from the late Prof. Physic—published by him some 40 years ago, and since frequently alluded to with the highest commendation in the writings of this country—it seems to have attracted scarcely any attention in Europe, or at least I do not find it noticed in the treatises I have consulted on the subject, with a solitary exception. *Cooper*, in his *Surgical Dictionary*, appropriates a paragraph to it, without praise or censure. The manner of application is, to place a narrow strip of epispastic plaster along the course of the vein as far as it appears to be inflamed, cutting an opening in it at the orifice, over which a soft poultice is to be placed, and the blister having drawn is to be so dressed as to be kept freely discharging," &c. Dr. C. also dwells on the importance of supporting the limb, so as to secure an absolute state of rest, and for this purpose recommends a nicely adjusted case, if the vein be in the arm.)—*Stephen Smith*, Phlebitis consequent on Otitis, *Ibid.*, July, 1851, p. 83.—*George B. Wood*, a Treatise on the Practice of Medicine, 2 vols. Svo. Phil., 1847, art. "Phlebitis."—*John Leil* and *W. Stokes*, Lectures on the Theory and Practice of Physic, Svo, 2 vols. VENEREAL DISEASES.—GONORRHEA—  
SYPHILIS.—SYNON. *Gonorrhæa*, *Blennorrhagia*,

*Phallorrhæa virulenta*; *Luës venerea*, Fernelius, Boerhaave, Juncker, Astruc, &c. *Syphilis*, Sagar, Vogel, Cullen, Pinel, Young, Swediaur, &c. *Syphilis venerea*, Sauvages. *Luës syphilis*, Good. *Syphilis*, Sprengel. *Scabies venerea*, Locher. *Luës syphilitica*, *Morbus Neapolitanus*, *Morbus Gallicus*, *Morbus venericus*, Auct. *Lust-scuche*, *Venerische Krankheit*, Germ. *Vérole*, *Vérole commune*, *Grande Vérole*, *Maladie Vénérienne*, Fr. *Mal Francese*, *lue Venerea*, Ital. *Poz*, *French Poz*, *Veneral disease*, *Veneral cachexia*.

CLASSIF.—III. CLASS, I. ORDER (Author in Preface).

1. DEFINIT.—Specific inflammations, or ulcerations, or both, affecting primarily the organs of generation of both sexes, and very frequently the whole frame, at subsequent and sometimes at remote periods, and propagated by contact.

2. Viewing venereal diseases as consisting of two very distinct forms—distinct in their primary character and in their consecutive effects—I shall very briefly notice, first, *gonorrhæa*, or *blennorrhagia*, or, more correctly, *Blennorrhagia specialis*, or *virulenta*, and afterward *syphilis*, or *Syphilis venerea*. The relations between these two venereal diseases have been for ages much discussed by both physicians and surgeons, and are not even now entirely disposed of. They, however, possess this in common, that they are primarily seated in the sexual organs, with very few exceptions; that they generally result from impure sexual connexion, or contact; that they are primarily either inflammatory, or ulcerative, or both; and that in many instances the frame becomes affected or contaminated by them, but in very different forms and grades, and much more frequently in the one form than in the other. These constitutional effects render them of equal importance to the physician and to the surgeon; and although both may sometimes require surgical appliances and aids, still they may be both cured by the prescriptions of the physician only, which alone are appropriate in the consecutive states of these maladies.

3. I. GONORRHEA.—SYNON.—*Phallorrhæa*, *Phallorrhæa virulenta*, *Gonorrhæa virulenta*, *Blennorrhagia*, *Blennorrhagia virulenta*.

4. DEFINITION.—A specific inflammation of an acute form, affecting the mucous surface of the urinary and sexual passages in both sexes, with a copious puriform or muco-purulent discharge, propagated by contact, and in some instances occasioning severe consequences.

5. I. DESCRIPTION.—I have shown, in the article VAGINA and VULVA, that those parts are often the seats of a purulent or muco-purulent discharge, which presents the following states or forms: 1st. *Leucorrhæa*, or *Blennorrhagia*, the discharge arising from irritation or inflammatory action, of a non-specific nature; 2d. *Acute Gonorrhæa*, or *Blennorrhagia virulenta*, the discharge being the result of a specific inflammation, caused by the contact of this discharge; and, 3d. *Chronic Gonorrhæa*, or *gleet*, the discharge being more mucous or less puriform, and generally consecutive upon the acute form; and unless when thus related, being distinguished with difficulty from *leucorrhæa* in the female; its contagious property being doubtful, unless the morbid matter acts on very predisposed parts. These forms and states of discharge are also met with in males. The first variety may be communicated by the

female to the male, or by the former to the latter, owing to the fact of puriform discharges, the result of inflammatory irritation of mucous surfaces, being capable of producing a similar state of morbid action in similar surfaces when these discharges are allowed to remain in contact with them. This result follows only in a few cases, and probably only when the recipient surface is predisposed to the infection. Thus a non-specific blennorrhagia, caused by excessive sexual intercourse, or by the discharges of the female organs, may be distinguished with difficulty from gonorrhœa, or acute specific blennorrhagia, and with still greater difficulty from chronic specific blennorrhagia, more especially when the acute specific disease is not very severe, or when it is a renewed or repeated attack.

6. *A. Gonorrhœa in the female* has been described in the article VAGINA and VULVA (see § 8, 38). The *chronic states* of the disease have been noticed by Mr. HOLMES COOTE in his very able work on the treatment of syphilis. He remarks, "that *chronic gonorrhœa* is a disease from which the lower order of prostitutes is rarely free. It exists also among the better class, who live highly, and drink without scruple. In general it disappears when the patient is kept on moderate and regular diet, and confined to bed; but it returns upon the least excitement," &c., and is perpetuated by some internal ulcer or abrasion, notwithstanding the treatment, until this latter lesion is cured. The irritating discharge often causes an abundant growth of *soft vascular warts*, commencing at the lower part of the vagina, near the orifice, and extending at the junction of the mucous membrane and the skin towards the superior commissure. "The rapidity of this growth is quite striking. When removed by the knife they return within a few weeks, if the irritating discharge be allowed to continue."

7. Among other cases adduced by Mr. H. COORE, showing that a female suffering from gonorrhœa may remain for months uncured, unless a proper examination be made, and some lesion beyond the reach of ordinary inspection be detected and treated in an effective way, the following deserves an especial notice. A young woman was admitted with a large growth of vascular warts from the external organs, and a copious puriform discharge. The usual means were applied, but they increased, and were removed by excision. The discharge, however, continued, a suitable treatment was prescribed, but the warts recommenced their growth, and the patient's general health declined. The os uteri was examined by the speculum, and it was found slightly ulcerated and abraded. Caustic was applied to this part. The discharge rapidly disappeared, the general health improved, and recovery was soon complete. In another case of chronic gonorrhœa, the usual remedies were employed with temporary benefit; but a recurrence of the symptoms invariably succeeded. When examined by the speculum, a large warty growth, soft, red, and vascular, was found two inches and a half from the orifice of the vagina. This growth was two inches in length, and an inch and a quarter across the base, springing from the anterior wall. It was removed by the knife; immediate relief, and complete recovery soon afterward, ensued.

8. *B. Gonorrhœa in the Male*.—This is not only a very painful and troublesome complaint,

but, if injudiciously treated, it may induce changes—or, rather, the treatment improperly adopted may occasion lesions unconnected with the disease, which may imbecile, or even shorten the life of the patient. And during a somewhat lengthened period of observation I can assert, that numerous instances have become known to me of attempts made to effect a speedy cure having been followed by the most distressing and dangerous results. The complaint usually commences from three to ten days after morbid contact; and the shorter the period of its incubation the more severe the attack; the stronger dose of the virus hastening the effects. A slight itching is at first felt, then an irritation at the opening of the urethra, and afterward a smarting pain, more or less severe, upon micturition. The lips of the urethra become tumid; a thin discharge, at first scanty, but soon afterward more copious and puriform, flows from the passage. The corpus spongiosum urethræ becomes thickened and unyielding, owing to inflammatory exudation into it; and when erection of the penis occurs, a bending downward, or chordee, is produced. Hæmorrhage sometimes takes place during this state and affords partial relief; and occasionally irritation extends from the urethra to the glands of the groin, causing slight swelling, which very rarely goes on to suppuration, except in scrofulous subjects.

9. A form of gonorrhœa—*gonorrhœa sicca*—is occasionally met with, both in the male and female, and has been described by Mr. ACTON and Dr. DUNN, in which the mucous membrane of the female organ is red, swollen, and tender, but free from discharge. In the male there are severe scalding and pain on passing the urine, painful erections, the lips of the urethra being red and swollen. This form of the disease has been called dry clap.

10. *C. Secondary Effects and Complications or Consequences of Gonorrhœa in Females*.—Owing either to neglect, to improper treatment, or to constitutional vice, or to neglect of proper regimen, several very serious consequences ensue upon the gonorrhœal disease. Most of those which occur in the *female* have been noticed in the articles UTERUS and ITS APPENDAGES (§ 43, 53, 122, *et seq.*), and VAGINA and VULVA (§ 8, 13, 38). These consequences are, chronic gonorrhœa, suppuration or abscesses in the labia, soft vascular warts (§ 6, 7), gonorrhœal inflammations of the cervix uteri, extending to the cavity of it and of the uterus along the Fallopian tubes to the ovaries, and even to the peritoneum; and, in rare instances, even to the uterine veins. Gonorrhœal ophthalmia and gonorrhœal rheumatism occur not less frequently in the female than in the male.

11. *D. The complications of gonorrhœa* sometimes observed in males are, 1st. *Balanitis* (from *Balanos*, glans), or *gonorrhœa externa*, is an inflammation of the surface of the glans and inside of the prepuce, with profuse purulent discharge and excoriation of the cuticle. This affection may be a complication of gonorrhœa, or may exist independently of it. In the former case it is produced by the gonorrhœal virus; in the latter by the want of cleanliness, and by the excoriations caused by the secretions of the part, which have become acrid by retention. In these latter cases the excoriations may be mistaken for chancre. 2d. *Phymosis* and *paraphymosis* occasion-

ally arise, owing to the swelling of the glans and prepuce. Oedema of the prepuce presents a semi-transparent or diaphanous appearance. These states, although often complicating gonorrhœa, not unfrequently occur independently of it, especially as a consequence of self-pollution; and in some instances they lead to very serious results. They furnish additional reasons, to others which may be adduced, as to the propriety of circumcision during infancy. 3d. Irritation or inflammation of the lymphatic vessels, extending to the glands of the groin, is a common association of the disease; but the affection of the lymphatics may be so slight as to be imperceptible, although the glands may be much swollen, inflamed, or even suppurate. 4th. The mucous follicles of the urethra may be inflamed and obstructed, and may even suppurate and burst either into the urethra, or externally, or both. In these cases very serious obstruction to the discharge of urine may occur. 5th. The inflammation may extend along the urethra to the prostate gland and neck of the bladder, and even along the ureters to the kidneys; or it may give rise to acute abscess of the gland and great suffering, especially during micturition, to strictures, &c. 6th. More frequently, inflammation extends along the vas deferens, causing swelling of the epididymis, or swelled testicle.

12. Gonorrhœa is always most severe on its first occurrence, and in young and robust subjects, and in the irritable and scrofulous constitutions and habits. In these it is often attended by severe inflammatory fever and disorder of the urinary functions; and it may even prove dangerous to life, by inducing extensive inflammation and abscesses in the vicinity of the prostate and bladder. "But after repeated attacks the urethra becomes inured to the disease, and each subsequent infection is generally (although not always) attended with fewer of the symptoms of acute inflammation. In some instances, the constitutional affection is extremely anomalous, and characterized by severe and continuous rigors," or by slight remittent or intermittent rigors and paroxysms of febrile reaction.

13. These complications, and more especially those about to be noticed, are chiefly to be ascribed to the local and constitutional influence of the virus or infecting agent, an influence manifested in some cases more prominently than in others, and not observed in cases of simple urethritis. Certain of the above complications are, however, merely the local extension of the gonorrhœal inflammation, often owing to the causes above alluded to. Other complications or consequences of the disease are of a constitutional and very serious nature. Mr. HOLMES COOTE, in a work published while this was being written, corroborates the view I have taken in the article VAGINA and VULVA (§ 8, *et seq.*), as to the specific nature of gonorrhœa. This very able and rising surgeon remarks: "Is the disease the consequence of the application of a simple irritating fluid to the mucous membrane, or is there a morbid poison acting on the parts locally, and capable of being absorbed into the system? I must confess there appears to me to be a most marked difference between simple urethritis and true gonorrhœa, as we daily see it among those exposed to contagion." Gonorrhœa in some cases occasions peculiar secondary affections, which never proceed from simple urethritis; and not only is

it occasionally followed by the local complications just mentioned, but also by one of the very severest forms of inflammation of the conjunctiva (see *art. EYE, Gonorrhœal Inflammation of*, § 56, *et seq.*), by the most severe and obstinate form of rheumatism (see *art. RHEUMATISM, gonorrhœal* (§ 44, 163), and by a form of papular eruption. The occurrence of purulent ophthalmia, or of rheumatism, or the extension of inflammation from the urinary bladder along the ureters to the kidneys, is of a most serious nature, as respects both the immediate effects and the more remote consequences.

14. ii. TREATMENT.—A. *Of Gonorrhœa in the Female.*—A copious use of diluents and demulcents; a farinaceous and vegetable diet; avoidance of fermented and spirituous liquors, and of salted provisions; a recourse to alkaline and refrigerant substances in mucilaginous drinks, and repose on a cool couch or mattress, are generally sufficient to remove the severer symptoms in a few days, especially when aided by the following local treatment judiciously advised by Dr. DRUITT: "During the acute stage, rest in the recumbent posture, fomentations of decoctions of poppy-heads with chamomile flowers, frequent abluion, lubrication with lard or cold cream, and very frequent sponging with a weak solution of alum, a piece of lint dipped in which should be inserted between the labia, with laxatives and diaphoretics, are the measures until heat, pain, tenderness, subside; afterward injections of nitrate of silver, and sulphate or acetate of zinc should be used, as recommended for the other sex, and they should be continued for some time after all discharge has ceased." (DRUITT'S *Surgeon's Vade-mecum*, &c., p. 175.)

15. If the disease becomes obstinate and chronic, the vagina and cervix uteri should be examined by the aid of a speculum, as the disease may be prolonged by lesions of the cervix or of its canal; and when this is the case, the means advised for such lesions, in the article UTERUS (§ 124, 125), should be resorted to. In chronic cases, the solution of sulphate of alumina, or decoction of oak-bark, or both conjoined, may be used as a lotion. Copaiba and cubeba may be given thrice daily in a mixture with mucilage, the spirits of nitric ether, and either mint-water or camphor julep, in the chronic, as well as in the advanced progress of more acute cases. In the former, preparations of iron, especially the tincture of the sesquichloride of iron, or the tincture of the ammonio-chloride may be preferred. In irritable and sanguine temperaments, camphor conjoined with nitrate of potash, with acacia and henbane, is often of much service, and may be prescribed in the form either of pills, of a mixture or draught.

16. B. *Treatment of Gonorrhœa in the Male.*—(a) Dr. DRUITT has advised, as a prophylactic treatment, that a person exposed to the chances of infection should wash out the anterior part of the urethra with a syringeful of some astringent lotion. I much doubt the complete success of this plan, or of the more usually adopted one of micturating immediately after sexual connexion: both plans may, however, be often successful. If any fissures or excoriations are perceived they may be touched with lunar caustic, and dry lint may be applied.

17. (b) *The abortive treatment of gonorrhœa*, or an attempt to cut short the attack by means

of strong injections, has been advised by some experienced surgeons. Ten grains of nitrate of silver, or four grains of the chloride of zinc, to the ounce of distilled water, have been prescribed with this object, when the disease is only commencing, and before scalding on micturition is experienced, or when the acute symptoms have passed. Mr. ACTON employs the nitrate of silver, and has recourse to only one or two injections performed by himself with due precautions. He never prescribed this treatment in cases of a first infection; and he states that he has not observed the injurious effects which have been supposed to result from it. For the modes of using, and the precautions to be taken when using, this treatment, I must refer the reader to Mr. ACTON's able work. Mr. HOLMES COOTE considers it not quite free from danger to the urethra; and he remarks that it should be remembered that it is in cases where the structures of the urethra are damaged that stricture occurs; the usual effects of gonorrhœa, in their acutest form, pass away, if not aggravated, without leaving any structural change. "At the commencement of the disease large doses of the tinctura ferri sesquichloridi, or of the citrate of iron and quinine, have been pronounced effectual in cutting short the discharge; and such remedies possess the advantage of inflicting no damage, if they do not produce the anticipated amount of good."

18. (c) *In the first or early stage of gonorrhœa* the antiphlogistic diet and regimen should be strictly enforced; and demulcents containing alkalies and refrigerants freely allowed, with the other means already noticed (§ 14, *et seq.*). Cooling aperients ought to be taken from time to time; walking and horse-exercise should be prohibited, and the patient confined to a cool sofa or mattress. The penis and scrotum should be supported by a suspensory bandage, and be kept constantly wet with tepid or cold water. If the acute symptoms have not appeared, M. RICORD recommends, according to Dr. Druitt, the following plan, in order to arrest the course of the disease: "Let the patient inject the urethra regularly once in every four hours, with a solution of two grains of nitrate of silver in eight ounces of distilled water; let this be repeated twelve times, desisting, however, sooner if the discharge is rendered thin and bloody, which is the ordinary effect of the nitrate. Then let an injection of the sulphate of zinc be substituted, and be continued until the discharge ceases. At the same time the patient should take a mild aperient, and after it, three times daily, a dose of copaiba or cubebs." He should continue a strictly antiphlogistic regimen for a week or ten days after all trace of the discharge has disappeared. The penis should be wrapped in a piece of rag dipped in water. Dr. Druitt proceeds to remark, that the "manner of injecting is of no small consequence, as the efficacy of the lotion depends entirely on its application to the whole of the diseased surface; and, as Dr. GRAVES observes, the ordinary opinion that gonorrhœa is limited to the anterior extremity of the urethra is unfounded and mischievous. The patient should be provided with a glass syringe, with a long bulbous extremity, and having filled it, should introduce it for about an inch with his right hand. Then, having encircled the glans penis with his left forefinger and thumb, so as to compress the urethra against the syringe, and prevent any of the

fluid from escaping, he should push down the piston with his right forefinger, letting the fluid pass freely into the urethra. The syringe should now be withdrawn, but the orifice should still be compressed, and the fluid be retained for two or three minutes; after which, on removing the finger and thumb, it will be thrown out by the elasticity of the urethra. It is always worth the surgeon's while to see that the injection is properly used."

19. (c) *In the second stage* the diet and regimen already advised should be continued. The patient may drink soda-water, barley-water, linseed tea, gum-water, and other mucilaginous fluids, containing alkaline carbonates and sedatives, and the bowels should be kept freely open. If much pain or chordee be complained of, the following pills may be taken night and morning, and the mixture occasionally through the day:

No. 372. R Camphoræ, ℥j.; Potassæ Nitratis, ℥ss.; Extr. Hyoscyami, ℥j.; Mucilag. Acaciæ, q. s. Misce et divide in Pilulas, xxxvj. Capiat duas vel tres pro dosi.

No. 373. R Potassæ Bicarbon., ℥ss.; Potassæ Nitratis, ℥ss.; Spirit. Ætheris Nitrici, ℥ss.; Tinct. Hyoscyami, ℥ij.; Mucilag. Acaciæ, ℥ss.; Syrupi Tolutani, ℥ss.; Mist. Camphoræ ad ℥viij. Misce. Sumantur Coch. ij. vel iij. ampla ter in die.

No. 374. R Liq. Ammoniac Acetatis, ℥j.; Spiritus Ætheris Nitrici, ℥ss.; Potassæ Nitratis, ℥ss.; Tinct. Hyoscyami, ℥ij.; Mucilag. Acaciæ, ℥j.; Syrupi Althææ, ℥vj.; Mist. Camphoræ ad ℥viij. Misce. Capiat Coch. ij. vel iij. larga 4tis vel 6tis horis.

20. The last of these prescriptions will be found serviceable in the most acute or inflammatory cases, and when the urinary organs become affected. In these cases a number of leeches should be applied to the perinæum, or above the pubes, or near the groins. In this stage of the disease injections should not be prescribed. For first attacks, and in young, strong, plethoric, or irritable subjects, they may be injurious. Refrigerants, diluents, demulcents, alkalies, and sedatives, are then chiefly required.

21. Dr. Druitt advises that the bowels should be opened by a dose of calomel at night, and some castor-oil in the morning; and that a grain or half a grain of calomel, and one eighth of a grain of tartar emetic, and ten grains of Dover's powder, should be given every night while there is much pain and chordee. As soon as the patient is free from fever, he should take copaiba or cubebs. The former, in capsules, may be given before a meal, as it is then not likely to cause eructations. Mr. ACTON prescribes copaiba and cubebs in the following combinations:

No. 375. R Bals. Copaibæ, ℥vj.; Magnesiae Calcinat., ℥ss.; Extr. Hyoscyami, ℥ss.; Pulv. Camphoræ, ℥j.; Theriacæ, ℥ij.; Mica panis, ℥ss. Misce. Fiat Electuarium. Capiat Coch. j. minimum ter in die.

No. 376. R Pulv. Cubebæ, ℥ss.; Bals. Copaibæ, ℥ss.; Extr. Hyoscyami, ℥ss.; Magnesiae Calcinat., ℥ss.; Pulv. Camphoræ, ℥ss.; Theriacæ, ℥j. Misce. Fiat Electuarium. Capiat Coch. j. min. ter in die.

22. The last of these is altered from Mr. ACTON's prescription, and the dose of camphor reduced one half. Cubebs, when taken in very large or frequent doses, generally diminishes the discharge, and remarkably relieves the other symptoms in a short time; but when employed alone, the disorder often returns after some time, especially if it be relinquished, or the dose much diminished. Cubebs should therefore be combined with copaiba, or other substances, in mucilaginous mixtures; or the tincture of cubebs may be substituted for the powder, as in the following draught:

No. 377. *R. Copaiba*, ℥xv.; *Mucilag. Acaciæ*, ʒjss.; *Pulv. Cubebæ*, ʒj. (vel *Tinctura Cubebæ*, ʒjss.); *Spirit. Ætheris Nitrici*, ℥xxv.—*Liquoris Potassæ*, ℥xv. *Aquæ Menthæ Piperitæ*, et *Mist. Camphoræ*, aa, ʒv. *Misce. Fiat Haustus ter in die sumendus.*

23. *d.* Several unpleasant complications occasionally appear in the course of this stage. Painful erections and chordee are the most common. They may be treated with tepid or cold application, and by narcotics and refrigerants given internally. Antimonials may be prescribed with small doses of camphor, nitre, and henbane or opium; and a little extract of belladonna, or lint wet with the tincture of belladonna, may be applied over the course of the urethra at bed-time. Hemorrhage from the urethra often affords relief. If, however, it becomes excessive, it may be readily checked by cold applications, and by pressure. Inflammation of the mucous glands, or in the cellular tissue external to the urethra, may be poulticed; and if abscesses form, they should be opened early, or as soon as they obstruct the flow of urine. Swellings of the glands in the groin are generally removed by rest, and seldom require the application of leeches.

24. *If Epididymitis*, hernia humoralis, or swelled testicle, supervene, Mr. H. Coore believes "that the best plan is to strap the testicle at once, after the fashion represented in the work of Mr. Acton. A layer of collodion over the strapping is often useful. The relief thus afforded to the patient is surprising, and the swelling will often subside to one half in twenty-four hours. The application of cold, either by cold lotions or by the careful use of pounded ice and salt in a bladder, tends to relieve pain, subdue the inflammation, and reduce the swelling. When in consequence of pain this treatment cannot be carried out, we may fall back upon the practice of leeching the testicles, and of administering emetics. Nothing reduces inflammation of these organs more promptly than this, but the treatment is severe. When induration remains after the acute stage has passed, pressure is more serviceable than frictions, whether of mercury or of iodine; both may, however, be employed." (H. Coore, *Report*, &c., p. 34.) Since 1824, for the cases respecting which I have been consulted, I have ordered an emetic, afterward an aperient, and the mixture (No. 374) last prescribed; and, two or three days afterward, full doses of the iodide of potassium in the above alkaline mixture (No. 373). Iodine is rarely of use when employed externally in this disease.

25. *d.* In the third stage, or when the acute symptoms have subsided, the injections advised in the first stage may be prescribed. If these fail, or if the discharge returns, injections with weak solutions of the sulphate or acetate of zinc or of copper, or of the bichloride of mercury, and with the addition of vinum opii, may be employed. These solutions should vary in strength with the circumstances of the case; but if either of these occasion severe pain, their strength ought to be much reduced.

26. If the disease becomes chronic, and passes into gleet, a long-continued treatment is generally required to remove it, however judicious the means may be. The habits of the patient should be strictly regular and temperate, and pills made with Venice turpentine, or with tar, or with copaiba and liquorice powder, may be employed. About thirty years ago I prescribed magnesia in the preparation of pills with these substances,

but they became so hard after a short time as to be often passed from the bowels undissolved. If these fail, camphor, with sulphate of iron, or with sulphate of zinc, kino, or catechu, and small doses of creasote, may be taken in the form of pills; or the tincture of the muriate of iron, with the tincture of quassia or of calumba, may be given in any suitable vehicle. If micturition be frequent or painful, or if the urine deposits any mucus, the preparations of buchu, pareira, and uva ursi, are generally indicated. In most of these cases the cold salt-water douche, or local bath, sea-bathing, regular and generous living, suitable tonics, and chalybeate mineral waters, will be of essential service. If the disease still remain obstinate, or if involuntary emissions occur, blisters to the perinæum, the introduction of a bougie, or other means which fall within the province of the surgeon, may be employed.

27. *e.* The diet, regimen, and beverages of the patient during acute, subacute, and chronic gonorrhœa, should be strictly enforced. In the acute and subacute stages, constant repose on a cool sofa or bed, and on a hair mattress; a diet restricted to vegetable or farinaceous food in very moderate quantity; the careful avoidance of active exercise, more especially of exercise on horseback, and of heating beverages. The fluids taken should be cooling and demulcent. Weak black tea, barley-water, weak veal soup, effervescing magnesia-water, or potash or soda-water, &c., may be allowed. In the chronic stage, or state of gleet, tar-water, spruce-beer, Dantzic spruce, the infusion or decoction of the tops of the spruce-fir, camphor-water, with nitre, &c., may severally be taken. They will tend to promote the effects of the medicines prescribed for this state.

[*Blennorrhagia*.—Acute inflammation of the urethra from gonorrhœal virus is usually combated successfully by an antiphlogistic regimen and saline cathartics, followed, if necessary, by injections of zinc, lead, or silver, as in the following formula: *R. Aq. Ros.*, ʒv.; *Sulph. zinc*; *Acet. plumb.*, aa, grs. viij. The patient, if the disease does not yield, should take half an ounce of the following electuary in the course of a day: *R. Copaiba*, 1 part; *cubebæ*, 2 parts; *ess. menth. q. s.*, ft. electuary. A bolus of this, covered with unleavened bread, is easily swallowed. About four ounces is generally sufficient to effect a cure; or, the copaiba may be given combined with the sirup of Tolu and oil of spearmint, and given in as large doses as the stomach will bear. As a general rule, the antiphlogistic regimen, baths, rest, and leeches to the perinæum, will effect a cure in the course of one week; and it is safer to trust to these for that space of time, before commencing with the indirect anti-blennorrhægics, copaiba, or cubebæ. Injections should never be resorted to at once; it is safer to trust to the above remedies for a reasonable time; if they fail, then resort to the above formula of zinc and lead, using it from two to four times a day. The nitrate of silver injection, in the proportion of one grain of the salt to six ounces of water, will also answer a good purpose. If chordee supervene, leeches should be applied to the perinæum, and camphor and opium administered in the form of pill, from two to six grains of the former, with from one half to one grain of the latter, two or three times a day. Cold applications to the genital organs, with laudanum, also afford great re-

lief; likewise mercurial ointment to the track of the urethra. Strict attention to hygiene is always necessary.

*Blennorrhæa*, or *Gleet*, is governed by the same principles of treatment as *blennorrhagia* or acute urethritis. It is generally a very obstinate affection, and requires a persevering use of remedies. Injections of sulphate of zinc, acetate of lead, nitrate of silver, and cold water will be indicated, but of a greater degree of strength; alum, tannin, and iodide of iron are also recommended as injections; blisters, also, to the urethra. The injections should be of moderate strength at first, and the strength gradually increased. BENJAMIN BELL advises half an ounce of sulphate of zinc to eight ounces of distilled water, using it several times a day. VIDAL uses from 15 to 30 grains of alum to two ounces of distilled water. A bougie, coated with an ointment of nitrate of silver, one grain to one drachm of lard, may be used, or with mercurial ointment, or the mercurial cerate, or 1 part ungt. hydrarg., and 2 parts extr. belladonna, or even the naked bougie may often be used with advantage. The bougie, according to VIDAL, should be large and soft, and introduced three or four times a day, sometimes for ten or twelve weeks together, and should not be discontinued till the cure is complete. If they cause an increase of irritation or inflammation, their use is to be discontinued. VIDAL remarks that a gleet which has resisted every kind of treatment occasionally disappears in an unknown manner—that there are some cases which resist every thing, even time, and which, after having been symptomatic of a form of inflammation of the urethra, are found at length to be maintained by strictures, disease of the prostate or bladder, or are complicated with seminal emissions. The treatment then, of course, has to be modified according to the complications of the case. Great caution should be used not to pass the bougie too deeply into the urethra, inasmuch as the disease is usually seated near the glans, and confined exclusively to that part.]

## II. SYPHILIS—*Siphilis*, Sprengel and H. Mayo. *Lues venerea*, Auct.

23. i. HISTORY OF.—Medical writings furnish no precise or undoubted accounts of this distemper until the appearance of the epidemic towards the close of the 15th century in the south, and soon afterward through all of Europe. In that and the following century, venereal eruptions occurred so commonly after infection, not only by sexual congress but also by contact, that the disease was regarded as a contagious malady affecting primarily and chiefly the skin. At the present day, and for a long time past, these eruptions and the other affections which sometimes accompany or follow them are much less frequent, and appear after a longer period from the primary infection than they did formerly. This circumstance, as well as some other modifications of the characters of the distemper, as described by the earlier writers, may be referred to the long transmission of the distemper by contagion, the venereal poison having thereby lost something of its original influence, and to its having, during many ages, been almost exclusively transmitted by the intercourse of the sexes, and without general infection, or not by the emanations or secretions from the secondary affections, unless under peculiar circumstances hereafter to be noticed (§ 109, *et seq.*).

28\*. As to the long-agitated subject relative to the early history of syphilis, it is quite unnecessary to enter farther than to notice a few of the authorities who have supported opposite opinions regarding it. GALESIUS (*De Podagra et Morbo Gallico*, 4to, Bon., 1637); BECKETT (*Philosoph. Trans.*, No. 357, 365); PLENK (*Beobachtungen*, &c., ii.); HENSLEY (*Geschichte der Lustseuche*, &c., b. i., 1783); KLEIN (*De Morb. vener. curat. in India Orientali*, Ham., 1795); STOLL (*Prælect.*, p. 94); THIERRY, RICHTER (*Chirurg. Biblioth.*, v. i., p. 163); and many others, have severally contended, but with insufficient evidence, for the existence of syphilis from remote antiquity, but in a sporadic form, before the discovery of America, and before its occurrence in an epidemic form at Naples in 1495. DE BLEGNEY even believed that it was known to MOSES; F. VALESIIUS (*Ann.*, iv., p. 57), that it caused the baldness and ulcerations of the face ascribed by TACITUS to TIBERIUS; LEFEVRE (*Hufeland, N. Ann.*, b. i., p. 309), that it had existed 800 years before COLUMBUS; SCHENCK (*Observat.*, l. vi., 217), that it had been observed as far back as 1270; ALCAZAR (*Haller's Biblioth. Med. Pract.*, ii., 197), that it was an ancient disease, and that it was epidemic in 1456; SCHAUFUS, that it was brought from India into Europe by the gipsies; CLAVERO (*Storia Antica*, t. iv., 1781), that it was not imported from America; and DELIUS, that it was an ancient malady, but was sporadic, and became epidemic by its complication with camp diseases at the end of the 15th century.

29. The first author who contended that syphilis was a variety of leprosy was M. CUMANUS, in 1495. He considered it identical with the leprosy of Campania, described in the 13th century by PAPIA of Lombardy. A similar opinion was entertained by S. AQUILANUS in 1497, by CAMPERIO, LANGE, BIONDI, and DODONEUS, early in the 16th century; and was supported by ZACUTUS LUSITANUS, MAYNWARING, and MUSITANUS in the following century.

30. That the distemper was brought from America by the followers of COLUMBUS was asserted by several writers in the commencement of and early in the 16th century, especially by N. POLL, L. SCHMAUSS, et U. AB HUTTEN, and by many others. This opinion as to its origin was very ably supported by ASTRUC and GIRTANNER (*Abh. von der Lustseuche*, &c.). It was, however, denied by SANCHEZ (*Abb. Ueber der Ursprung Venussenche*, &c., Bremen, 1775), who argued that an indigenous malady could hardly be brought to Europe and there become epidemic; by SARMICUTO (*loc. cit.*, i., p. 67); and by HENSLEY (*Geschichte der Lustseuche die zu Esde dis. 15. Jahrh. in Europa Ausbrach.*, Altona, 1783). More recently DESRUELLES (*Op. cit.*) has contended for the antiquity of the disease, and denied the importation of it from America. DESPORTES (*Hist. de Malad. de St. Dominique*, t. ii., p. 61), LAGRANGE, SLOANE, and numerous others, however, have shown that a disease resembling syphilis was prevalent in Hispaniola when visited by the Spaniards, and was brought into Europe by them from 1493 to 1495. ASTRUC states that in the Neapolitan, or rather in the Spanish army, there were not a few of the soldiers who, returning from the Indies, either in the first voyage with COLUMBUS, in the month of March, 1493, or in the second with A. DE TORREZ, in the beginning of 1494, or in the third with P.

DE MARGARIT, at the end of the same year, were still infected with the venereal disease, or at least had contracted it in Spain, after it had been brought by others into Europe. And therefore it is by no means strange that many of the Neapolitans should be infected with the same distemper, as they served under the same colours, and conversed with the same females who followed the camp. Hence he concludes that the disease was communicated from the Spaniards to the Neapolitans, from both to the French, and from all three to the other European nations, and to most of the people of Asia and Africa; though he believes that, under the torrid zone, there are some countries where it seems to have been a native and an endemial disease. (*De Morbis Veneris*, vol. ii., 4to, Paris, 1740, lib. i., cap. &c.) SANCHEZ DE RIBEIRO, in 1765, contended that syphilis originated in Europe, and assumed the epidemic form in 1493. He was the first to shake the belief in the American origin of the malady, and was followed by HENSLEY, who believed it to have been intimately connected, in origin and nature, with the leprosy of antiquity, which he regarded as the precursor, in Western Europe, of syphilis at the end of the 15th century. RICHTER (*Chirurg. Biblioth.*, b. i., p. 163), however, contends that syphilis was an ancient disease, and was imported into America by the Spaniards. But there is no sufficient evidence of such importation by the Spaniards, whereas evidence is furnished by ASTRUC and others that a similar distemper was prevalent in the West Indies and America among the natives when first visited by COLUMBUS, and that they treated it with the same medicines as they found most successful subsequently by the Spaniards and other Europeans. That this distemper existed in America, in Western Africa, and probably also in other intertropical countries, before the discovery of America, appears to have been conclusively shown by numerous writers, although in more or less modified forms, according to race, modes of life, and numerous circumstances; and that it still exists in these forms, as a most prevalent and contagious distemper, in these countries, cannot be doubted. It was considered as being not improbable that the milder states of the disease prevalent in some of these countries, and in Hispaniola, when first visited by the Spaniards, assumed in the latter, as well as in other Europeans, a much more severe character, especially when they became associated with scurvy, or with leprosy, then so prevalent in Europe, or with other epidemic or endemic diseases, or when the distemper first infected different races from those in which it had first originated, using different kinds of food, adopting different modes of living, and observing very different social and domestic habits, &c. That the disease is modified by these causes, by climate and by treatment, even at the present day, cannot be disputed; and hence, most probably, it may have resulted from those distempers, which are denominated syphiloid by several writers, which are characterized by the most prominent features of constitutional syphilis, and which are different forms of syphilitic cachexia, arising out of those circumstances, in connexion with differences of race, with climate, habits of life, modes of communication, &c. (§ 84, *et seq.*).

31. In addition to these opinions as to the history of syphilis, another had been from an early

period entertained by several writers, but had received little attention until it was supported by D. C. G. GRUNER, who has inquired into the early history of syphilis with great learning and candour; and has described the symptoms of the disease, as it appeared in Italy in 1493 and 1494, and the ways by which it was propagated. From his account, or rather, according to the authorities he has adduced, it appears that syphilis was then a much more acute, rapid, severe, and complicated distemper than in modern times; and that it was communicated in its several constitutional forms, not only by sexual intercourse, but also by kissing, by sleeping in the same bed, by contact, especially with parts covered by eruptions, by shaving with the same razor, by drinking from the same vessel, by inhaling the breath of the infected, by the clothes, particularly woollen, of the diseased, and even by contact of any part of the body. The sudden appearance and rapid extension of the malady the medical men of the day were at a loss to account for. As to the opinion that diseases of the genitals were at all times an occasional or sporadic result of impure sexual connexion, GRUNER remarks, "Hoc quidem certum ac indubitatim est, homines nunquam sibi temperasse a venere vulgivaga, ideoque ab historicis stupenda narrari exempla, quin sub finem seculi xv increbrescere vitia genitalium veneris similia, sed ea fere leprosa. Ille vero, nisi de verbis disceptare volumus, ut ferri quidem et defendi possunt, ita etiam corpora fuisse apta ad recipiendam contagionem affinem satis declarant. Medici enim et chirurgi horum temporum bene versati in cognitione morborum cutaneorum, cum maximè lepræ, tantum non omnes novitatem morbi mirantur et stupent, et similitudine quorundam symptomatum opinantur eam esse lepræ proximam, vel in eam tandem transire; leprosi vero Gallico morbo correptos cane pejor ac angue fugiunt et procul abesse jubent. Ex hoc, ni omnis fallor, certissime colligitur, fœdum morbum non fuisse omnino eundem, sed paullo diversum et a causa quadam insolente productum. Quam in venere impura per se latuisse vix affirmandum est." (*Op. cit.*, xv.)

32. GRUNER contends that the opinion as to the introduction of syphilis in Europe from America cannot be sustained, inasmuch as it cannot be shown that the distemper was in 1493 endemic in America in the form in which it existed in Italy; that, if the foul ulcers and buboes observed in the latter existed in the former country, they should have been manifest in those aborigines brought to Europe; and that a malady imported into Spain by a few individuals from America, could not in the same year have been transmitted to Italy and there so rapidly spread the devastation which it was said to have produced. He therefore asserts that the evidences furnished by FULGOSUS, SABELLICUS, NAUCLERUS, LEO AFRICANUS, and others respecting the expulsion of the Moors and Jews from Spain in 1492, and in the five preceding years, and the fearful distresses and distempers consequent upon this expulsion are sufficient to account for the appearance and rapid dissemination of syphilis in Italy and in other countries. These writers state that the disease was brought from Africa into Spain, and that, when FERDINAND expelled the Moors and Jews from Spain, from 1487 to 1492, it assumed a severe and epidemic form, owing to the distresses experienced by these emigrants. It is expressly stated by NAUCLERUS, "In itinere abe-

untium Judæorum triginta millia pestis absumsit. Eodem tempore etiam Marrani (Moors) Romæ ad portam Appiam morati effleerunt, ut incontinenter pestis invaserit urbem, mortuique sunt quam plurimi ex peste et contagione dietorum Marranorum, de quibus tota urbs impleta est." GRUNER therefore infers from these and other authorities that the diseases to which the genitals were liable, owing either to impure connexion or to leprosy or other causes, were developed into a pestiferous form by the distresses and other circumstances connected with the expulsion and emigration of the Moors and Jews, that the distemper in this malignant form was disseminated throughout Italy—the French army which invaded Italy in 1493, bringing it with them on their return to France, and that it spread rapidly from thence and from Italy to other countries.\*

\* As it is manifest, in the present state of our knowledge, that syphilis is caused by a specific poison or contagious agent, originating, as far as we know, in the secretions of the sexual organs, and generally communicating the disease by sexual intercourse, but sometimes also by contact under different circumstances, and in different stages of the malady, and even to the fetus; that syphilis will not produce gonorrhœa, although both diseases are often associated; and that gonorrhœa will not give rise to syphilis, although like syphilis it is generally caused by sexual intercourse, but capable of being propagated by contact in other ways; so it follows that conclusions respecting the origin of the one disease cannot apply to that of the other. For being thus distinct, although sometimes associated, and generally propagated in the same way, it is very probable that these distempers may have originated in different epochs and in different circumstances. Admitting that syphilis was brought into Italy in 1493 by the Moors and Jews expelled from Spain, when it was developed into an epidemic and an acute distemper either by the sufferings and other circumstances of these emigrants, or by its being engrafted on or becoming associated with some other malady, as leprosy, camp fever, scurvy, &c., according to the evidence furnished by GRUNER; or that syphilis was imported in the following year into Europe from Hispaniola, where it had long existed as a specific disease, although manifesting various modifications in its primary and consecutive phenomena both there and still more remarkably in Europe, still there appears to be no sufficient evidence that gonorrhœa, also a specific disease, and known now as such, and existing most frequently unconnected with syphilis, either first appeared in connexion with this latter distemper, or existed previously to it. It is certain, however, that from an early period of the certain history of syphilis, or early in the 16th century, gonorrhœa was mentioned as a frequent complication, or prominent symptom of syphilis. It is very difficult to determine any thing conclusive as to the origin of virulent or specific gonorrhœa, as most probably a puriform discharge was not an uncommon result of impure connexion, or of sexual intercourse with unclean, leprosy, or otherwise diseased females in the early and middle ages. The descriptions of disease by most of the writers of these ages, as well as of those of the 15th and 16th centuries, are so vague as to give rise to grave doubts as to their precise application, and although some of the accounts given by authors long before the period at which this distemper was developed in Italy seem to apply to gonorrhœa, yet their accounts are not complete in some respects, and fail in mentioning the association of a copious discharge, and of certain other contingent symptoms and consequences of the disease, although other symptoms which are certainly characteristic of it are fully stated.

1. *The testimonies* which have been adduced as to the existence of SYPHILIS in Europe before the discovery of America have been considered as conclusive by BROOKER, HENSLEY, SWEDIAUR, B. BELL, DESRUELLES, and altogether insufficient by ASTROC and numerous writers in the 16th and 17th centuries. I may notice the following among the former: GULIELMUS DE SALICETO, in 1270, states (in l. i., cap. 42, *De Apostemate in inguinibus*), "Hæc ægritudo vocatur bubo vel dragonella inguinis vel apostema inguinis" \* \* \* et aliquando cum accedit homini in virgâ corruptio propter concubium cum foeda muliere, aut ob aliam causam. Itaque corruptio multiplicat et retinetur in virgâ, unde non potest natura mundificare virgam aut locum, primò propter multam plicaturam partium illarum et propter strictam viam illius loci, unde redit et regurgitat materia ad locum ingulum propter habilitatem loci illius ad recipiendam

33. The question still remains unanswered as to the origination of the syphilitic disease brought

superfluitatem quamlibet, et propter affinitatem, quam habent hæc loca ad virgam."—Cap. 48. "*De Pustulis albis vel rubris, et de Miliis et de Scissuris, et de Corruptiõibus vel hujusmodi, quæ fiunt in virgâ vel circa præputium propter coitum cum foetida muliere, aut cum meretrice, aut ab aliâ causa.*"

LANFRANC, of Milan, in 1209 (*in Artis Complete Chirurgiæ*, tract. iii., doct. ii., cap. 11), asserts: "Sæpe provenire apostema in inguine propter ulceram virgæ et pedum, propterea quod locus est descensus humorum ad illa loca, et tunc non est ita timendum, propterea quod venire tunc potest sine multâ corporis plenitudine, et absque eo quod decursus humorum maxime ibi fiat." In tract. iii., doct. iii., cap. 11, *De Ficu, et Cancero, et Ulcere in virgâ virili*, he adds: "Ficus est quedam excrecentia, quæ nascitur supra præputium virgæ, et aliquando super caput, quæ quidem aliquando est mollis, ut de phlegmatica generata materia; aliquando dura ut de Melancholici; quæ si corruptatur, transit in cancerum. Cancer fit in virgâ, sicut in aliis diximus fieri membris: ulcera veniunt ex pustulis calidis virgæ superveniuntibus, quæ postea crepantur; vel ex acutis humoribus locum ulcerantibus; vel ex commissione cum foetâ muliere, quæ cum egro talem habente morbum de novo coherat."

BERNARD GORDON, in 1300, Professor of Medicine at Montpellier, remarks (*Lib. Med.*, part vii., cap. 5, *De Passionibus Virgæ*): "Passiones virgæ sunt multæ, sicut sunt apostemata, ulcerationes, canceri, inflatio, dolor, pruritus. Causæ sunt exteriores aut interiores. Exteriores, sicut casus, percussio, et jacere cum muliere, ejus matris est immunda, plena sanie, aut virulentia, aut ventositatis et similibus corruptis. Si autem causa fuerit intrinseca, tunc sunt sicut humores corrupti, et mali descendentes ad virgam, et ad partes inferiores, inducentes prædictas passiones."

JOHN OF GADSDEN, in 1310 (*Rosa Anglica*, cap. de curâ ulcerum virgæ), states: "Ulcera virgæ virilis contingunt vel ex coitu cum juvenicula, vel ex coitu cum menstruatâ, vel ex retentione urinae et spermatis."

GUIDO DE CALIACIO, of Montpellier, in 1360 (*Chirurg. Maj.*, tr. vi., doct. ii., cap. 7), has a chapter, "*de Calefactione et Fœtitudine in virgâ propter deubitum cum muliere foetida.*"

VALESCHUS DE TARANTA, Professor of Montpellier in 1400 (*Phil.*, l. vi., cap. 6, *De Ulcibus et Pustulis virgæ*), describes these as follows: "Causæ possunt esse primitivæ, aut antecedentes, aut conjunctæ. Primitivæ, ut est vulnus, vel attritio, vel coitus cum foetida, vel immunda, vel cancerosa muliere; alia causa potest esse portasse femoralia nigra, foetida et immunda; alia causa potest esse materia spermatica vel corrupta retenta inter caput virgæ et præputium, vel mali humores ibidem retenti, qui ibi retenti et non evacuati corrumpunt locum, quem tangunt, vel ulcerant." And again towards the end: "Pustule virgæ fiunt, si quis coeat cum feminâ habente ulcus in matrice, quæ contagio sitate sua inficit virgam, et in eâ facit ulcus."

PETRUS DE ARZELATA, of Bologna, in 1470 (*Chirurg.*, l. ii., tr. xxx., cap. 3. *De Pustulis, quæ adveniunt virgæ propter conversationem cum foetâ muliere, quæ albe sunt vel rubra*) writes: "Ex materiâ venosâ, quæ retinetur inter præputium et pellem virgæ causantur istæ pustule tales per hunc modum, quoniam ex retentione illius materię, quæ remanet inter pellem et præputium, ex actione viri cum foetâ muliere, quæ non respirat pntrofit; deinde ille locus denigratur et mortificatur substantia virgæ, quæ restaurationem non recipit, nisi corruptione illâ remotâ, et loco absterso." And then after prescribing certain detergent, styptic lotions, &c., for the cure of those pustules, he thus goes on: "Unum recorder vobis, quod antequam ista balnea dicta (or lotions) ex vino illo styptico fiant, fiat purgatio, aliter illis bubo superveniret in inguine, quoniam materia quæ venit ad locum illum retroPELLITUR à balneo isto (or rather lotion) et inveniens concavitate inguinis illic moram facit; quare bubo generatur ad exitum pluries devenit. Quare purgationem universalem facias; et imperiti medici sperantes indiscretè vel incautè non faciunt purgationem, quare duplici modo luerantur, quoniam de virgâ et bubone. Iterum viri tales debentes materiam venientem ad locum resolvare, querunt illud sanare ut aliquid luerentur, et hoc non debet fieri à discreto homine et magistro."

That the above brief notices of ulcers on the penis and buboes in the groins refer to syphilis can hardly be credited, unless consecutive constitutional disease had also been described; but of this latter no evidence is furnished. However, it may be stated by the abettors of the non-mercurial treatment that these sores were actually venereal or syphilitic, no secondary symptoms appearing, owing to the strictly local or non-mercurial treatment adopted for their cure. Among the first writers who de-

by the Moors and Jews from Spain into Italy. It has been, as stated above (§ 30-32), acknowledged

scribed the venereal disease, which appeared at Naples in 1494 or 5, and became epidemic over Italy, and rapidly spread throughout Europe, were MARCELLUS CUMANUS, NICOLAUS LEONICENUS, and CORADINUS GELINUS. Their works on this disease appeared in 1496 and 1497, and were followed by other productions in this latter year, in 1498 and in 1500, and in almost every successive year down to the middle of the 16th century. The writers were chiefly Italians, who describe the symptoms and treatment of the disease, assert it to have been an unknown malady previously to 1495, and speculate variously respecting its prevalence and rapid extension.

From these descriptions it is manifest that the distemper was virulently contagious; that it was communicated not only by sexual intercourse, ulcers appearing on the genitals, and followed rapidly by the most severe constitutional symptoms, &c., but also by contact of any part of the body of those infected, and by fomites, &c. Those who are desirous of becoming acquainted with the early history of this distemper—the most important chronic malady which infects the human frame—will consult with advantage the collection of early treatises on *Lues Venerea*, formed by ALOYSIUS LUTSINUS, under the title *Aphrodisiacis sive de Lue venerea, continens omnia quæcumque de hac re sunt ab omnibus Medicis conscripta*, 2 vols. in fol., Lugd. Bat., 1723. The dates of the first appearance of these treatises are, however, not always given by LUTSINUS. A *Supplement* to this work has been added in historical order by C. G. GRUNER, entitled *Aphrodisiacis sive de Lue venerea: ejus vestigia in Veterum Auctorum monumentis, et quos A. Lutsinus Onisit Scriptores*, fol., Jenæ, 1789; and the following work, by the same author, will be perused with some interest: *De Morbo Gallico Scriptores Medici et Historici, partim inediti; aecedunt Morbi Gallici Origines Maraniceæ, Collegit, edidit, glossario et Indice Auxit.* Svo, Jenæ, 1793. DANIEL TURNER published an abridgment of the folio volumes of A. LUTSINUS, under the following title: *A Summary of the Ancient Writers on the Venereal Disease, extracted from his two Tomes, revised by BOERHAAVE, with Index of those omitted.* Svo, Lond., 1736.

II. As the identity of syphilis and gonorrhœa, formerly contended for by some and denied by others, is now satisfactorily disproved, although in the present day most commonly resulting from impure sexual intercourse, it follows that the evidence furnished respecting the period in which syphilis first appeared in Europe cannot be viewed as comprising also the time when gonorrhœa made its first appearance—or that the proofs as to the historical origination of the one could be extended to, or be considered as conclusive of, the same origination of the other, either as to time or to place. In the earlier histories, however, of cases of syphilis, gonorrhœa was often mentioned as a prominent symptom.

In the *Statutes* which JANE I., Queen of both the Sicilies, directed to be formed for the regulation of the public stews, established at Avignon in 1341, it is enacted (*Stat. iv.*) as follows: "The Queen commands that, on every *Saturday*, the women in the house be singly examined by the abbess and a surgeon appointed by the directors, and if any of them has contracted any illness by their whoring, that they be separated from the rest, and not suffered to prostitute themselves, lest the youth who converse should catch their distempers." This statute may be viewed as applicable to either venereal disease, or to neither; for it has been contended that sexual intercourse with a female during the catamenia, or suffering under leucorrhœa, with a leprosy female, during the Middle Ages, or even in more recent times, when personal cleanliness was not so much attended to as now, would produce a sexual disease capable of propagation. That the malady which the above statute was intended to abate might have been gonorrhœal is not improbable, although no sufficient proof of its existence appears.

MR. BROKET (*Philosoph. Trans.* No. 357, ann. 1715) has endeavoured to prove that a venereal gonorrhœa was known in England some ages before 1494, under the names of *Ardor*, *Arsura*, *Incidium*, &c., and in English of *Brenning*, or *burning*, and described as an *inward heat* and *excoriation of the urethra*. This affection is treated of by JOHN OF GADDESSEN in his *Pract. Med. seu Rosa Anglica*, in a chapter, "*De Infectione ex Conubitu cum leproso vel leprosa*;" and he there states: "Illum, qui concubuit cum muliere, cum quâ coluit leprosus, puncturas intra carnem et corium, hoc est inter balanum et præputium, et aliquando calcificationes in toto corpore sentire." "That this scalding might or might not arise from the cause here stated is equally probable, but it cannot be viewed as a proof of the existence of gonorrhœa, inasmuch as no mention is made of its coexistence with a copious muco-purulent discharge. That the time and the circum-

stances of the origination of gonorrhœa are not without some interest, will appear from the fact of this complaint being viewed by many recent writers as in no respect different from leucorrhœa, or blennorrhagia, according to modern nomenclature. In Africa, as I was able to learn from Moorish and other native physicians, gonorrhœa was viewed as a distinct disease, although often complicated with the yaws or syphilitic affections and with leprosy, and was viewed with syphilis, as possessing an antiquity as great as that of leprosy (see § 84, 85).

Whether gonorrhœa made its first appearance in Europe at the close of the 15th century, or previously to this period, admits not now of satisfactory proof; nor even do we now know at what time it was first viewed as a variety of the venereal disease, or at least intimately connected with syphilis. Astruc remarks that all the physicians who lived in the close of the 15th and beginning of the 16th centuries were unanimous in their opinion that the venereal disease was a new distemper; but they entertained very different notions as to its origin.

The earliest writers believed the malady to have arisen from the influence of the stars, or certain conjunctions of the planets; others that it proceeded from the state of the seasons in connexion with fortuitous circumstances; some that it was an offshoot of leprosy, or that it arose from the connexion of healthy with leprosy persons; a few that it was the result of unnatural or unclean sexual intercourse, or of bestiality; and many that it was indigenous or endemic among the natives of Africa and America; but it does not appear to what they attributed the origin of the disease in these countries. (*See the Chapter on syphilitic diseases, or affections closely allied to syphilis.*)

It has long been the practice, especially with European writers, to attribute the origin of syphilis to the American continent, and that, too, in opposition to all well-attested facts connected with its true history. The first writers in Europe who described the disease say not a word in regard to its transatlantic origin, but attribute

34. But admitting that *syphilitic diseases* (§ 32) actually prevailed both in America and in Africa

it either to a celestial influx, a malignant conjunction of Saturn and Mars in the sign Scorpio, Divine vengeance, an earthquake, or a malignity of the air caused by an overflow of the Tiber, &c. Lord BACON, following FIORAVANTI, believed it to have been generated by the use of human flesh as food at the siege of Naples. The first writer who suggested its American origin was LEONHARD SOMMATUS, a German physician who wrote in 1513, twenty-five years after the disease first appeared in Italy; and he was followed by ULRICH VAN HULTEN, OVIEDO, and others on the same side, so that in the space of fifty years the American origin of syphilis was received very generally as a well-established fact in history. They unite in the statement that the disease was imported into Europe by the crews of COLUMBUS on his first or second return home, in 1493 and 1496, "a belief," says Dr. GOOD, who seems to have investigated this point with great industry and impartiality, "which seems to be altogether without foundation; for, at the period even of the first return of this celebrated circumnavigator, in March, 1493, it seems to have preceded his return by some weeks' time. On his reaching Seville in the ensuing month of April, in order to join the Spanish army, it had already arisen, and was spread over Auvergne, Lombardy, and various parts of Italy; as in the course of the summer months it was observed in Saxony, Brandenburg, Brunswick, Mecklenburg, and especially Strasburg, as all the German writers concur in admitting; and even at Cracow, in Poland, according to STREYKOWSKY's 'Chronicle of Lithuania.' While FRACASTORIO, who was an eye-witness of the entire progress of the disease, and from his high medical reputation, and residence almost on the spot of its first appearance, more largely engaged in the cure of it than any physician of his day, asserts that it was even ravaging a considerable part of Asia and Africa, as well as of Europe." Not only this writer expresses his disbelief in the disease having been imported from America by the crews of COLUMBUS, but not a single writer who was an eye-witness of the first outbreak of syphilis ascribed to it an American origin; nor did COLUMBUS, nor his brother, who left such accurate narratives of his voyage, make the least mention of such a disease having been discovered among the natives, or prevailing among the crews of their vessels. Moreover, we have the testimony of FULGONI that it prevailed in Upper Italy in the year 1492; of SABELLICO, INFESSERA, DELPHINI, and FULGONI that it prevailed in Upper Italy in 1493; and of MASSA, CATANEO, PINETOR, BURCHARDI, and CAPELOTTI, that syphilis prevailed extensively at Rome and in Italy in 1494. Now CHRISTOPHER COLUMBUS, on his first return to Europe, landed on the 4th of March, 1493. The statement, therefore, of OVIEDO, that this disease was carried to Italy by the army of GONZALVO must fall to the ground, inasmuch as this general arrived at Calabria as late as the month of May, 1495. OVIEDO has always been the great authority on this point, but he was charged and convicted of the grossest falsehoods, contradictions, and inaccuracies, by his contemporaries FERDINANDO COLUMBUS, A. HERREIRA, DE LA CASA, and others. There is, indeed, not a shadow of evidence that syphilis existed in America till the third voyage of COLUMBUS, in 1498, when it was probably carried to St. Domingo by his crews, and five years after it had prevailed extensively in Europe. If any thing more be wanting to confirm the belief that syphilis did not even exist in the West Indies and on the continent of America at the period of their discovery by the Spaniards, it may be found in the following letter, from our distinguished countryman, WILLIAM H. PRESCOTT, the historian, to Dr. A. E. HOAG.

"Boston, Jan. 22d, 1844.

"MY DEAR SIR,—I have received your note of the last week, inquiring whether in my researches relative to the history of Mexico, I had met with any trace of the existence of the venereal disease among the aborigines previous to the coming of the Spaniards. \* \* \* In a note in the 'History of Ferdinand and Isabella,' vol. ii., p. 501, I took occasion to express my own conviction that the venereal disease did not exist among the natives of America at the time of its discovery. I had met with no allusion to it in the narratives of Columbus or his son Ferdinand, or in any other record of the Spanish adventures. I have been led into a much wider range of observation in preparing the 'History of the Conquest of Mexico,' but it has served to confirm my former opinion, since I have never met with a notice of this disease, or of any which resembles it. The ancient chronicles speak of an Indian epidemic, called the *Matlazahuatl*, which swept off great numbers of the nations both before and after the conquest, and which seems to have had some resemblance to the Yellow Fever. They also notice the introduction of the small-pox by a black, who came into the country the

for ages before the discovery of COLUMBUS, it does not follow that the disease brought by his followers from America was the cause of the epidemic syphilis of Italy and other countries in 1493, 4, and 5. Indeed this inference is completely disproved by facts; for, as SPRENGEL has contended, syphilis, according to the testimony of most reputable authors, had appeared early in 1493, and soon afterward extended to most of Europe, while, according to OVIEDO, the most credible of all witnesses on the subject, the fleet of GONSALVO, which conveyed the Spanish soldiers to Italy, arrived in Messina on the 26th of May, 1495. Thus the disease was existing two years before the arrival of the Spaniards, and spreading in the army of Charles VIII. of France. That the disease existed in Barcelona in 1494 or 5, appears in a letter published by THUENE, from NICHOLAUS SCYLLATIUS, a physician of Messina, the editor of an edition of the "*Rosa Anglica*," in 1492, and addressed to AMBROSIVS ROXATUS, physician to the Duke of Milan. From this letter it appears that SCYLLATIUS was in Barcelona in 1494, that the distemper was spreading among all ranks, and was propagated by contact only, and that it was universally believed to have proceeded from Provence, where it was named the disease of St. Ment. SCYLLATIUS thought it the *sahafathi* of AVICENNA; but while he describes its general characters, he says nothing, as may

year after the arrival of Cortez. The Spaniards would certainly not have omitted to notice so terrible a disorder as the venereal, had it been found among the natives; especially as, considering their own licentious Indulgence, it must have fallen very heavily on themselves. Their uniform silence, therefore, is evidence so strong, that it may be called positive rather than negative, and may be considered as establishing the fact that the disease was not known in the Mexican empire at the time of its discovery. Whether a disease so easily propagated among adjacent tribes, and which seems to be circumscribed by no parallel of latitude, could have existed in other parts of the continent without finding its way into Mexico, is a question which your own knowledge of the subject will enable you to determine better than I can.

"W. H. PRESCOTT.

"A. G. HOAG, Esq."

The following extract from "Ferdinand and Isabella" gives the paragraphs referred to above by Mr. PRESCOTT: "While the colonial commerce failed to produce immediately the splendid returns which were expected, it was generally believed to have introduced a physical evil into Europe, which, in the language of an eminent writer, 'more than counterbalanced all the benefits that resulted from the discovery of the New World.' I allude to the loathsome disease which Heaven has sent as the severest scourge of licentious intercourse between the sexes, and which broke out with all the virulence of an epidemic in almost every quarter of Europe, in a very short time after the discovery of America. The coincidence of the two events led to the popular belief of their connexion with each other, though it derived little support from any other circumstances. The expedition of Charles the Eighth against Naples, which brought the Spaniards, soon after, in immediate contact with the various nations of Christendom, suggested a plausible medium for the rapid communication of the disorder; and this theory of its origin and transmission, gaining credit with time, which made it more difficult to be refuted, has passed with little examination from the mouth of one historian to another to the present day.

"The extremely brief interval which elapsed between the return of Columbus and the simultaneous appearance of the disorder at the most distant parts of Europe, long since suggested a reasonable distrust of the correctness of the hypothesis; and an American, naturally desirous of relieving his own country from so melancholy a reproach, may feel satisfaction that the more searching and judicious criticism of our own day has at length established beyond a doubt that the disease, far from originating in the New World, was never known there till introduced by Europeans."—(*The N. Y. Journ. of Med. and the Collateral Sciences*. Edited by S. FORRY, M.D., vol. ii., New York, 1844, p. 150.)]

be expected from the date of his letter, of an American origin.

34\*. It is difficult if not impossible to determine accurately either the place or the date of the first appearance of syphilis in Europe. So rapidly did it manifest itself in one place after another, that it is impossible to determine the place in which it was first recognised. FULGOSUS states that it appeared in Italy as early as 1492; PETRONIUS, C. TORELLA, HASCHARD, ULRICH DE HUTTEN, and BORGARUTIUS, in 1493; JOHN DE VIGO, MASSA, CATENEUS, HOCK, SCHMAUSS, FALLOPIUS, and many others, in 1494; BRASAVOLUS, in 1495; PHISIUS, MONTESAURUS, MAINARD, BENIVENIUS, and MONTANUS, in 1496; and FRACASTORIUS as early as 1490. It should not be overlooked that these and other authors evidently assigned these dates as the times when the disease became known to them, or in the places where they wrote, or they took the dates from the testimony of others. Wherever or whenever it first appeared, it cannot be disputed that it was speedily evinced in the chief cities of Europe. That it was seen as early as 1490, according to FRACASTORIUS, or 1492, as stated by FULGOSUS, may be inferred from the circumstance of its having been mentioned in the Mansfield Chronicle, in the Leising Chronicle, the Leipsic Annals, and the Zweifalt Annals, as being general in Germany in the summer of 1493; "and it is even said to have prevailed at least four years in Misnia. It was common in Auvergne in 1493. It was known in Paris in 1494, and in Augsburg in 1495." It appeared in Memmingen, at Nürnberg, and in Edinburgh, in 1496; and it spread through Bohemia in 1499. It has been considered remarkable that the Chronicles of Barcelona, Valence, Murcia, Toledo, Seville, Burgos, Guadalajara, Valladolid, Segovia, and other cities in Spain, have made no mention of the period at which the disease first appeared, and the same is true of the cotemporaneous annals of Portugal. The opinion which I have expressed (§ 112), that this distemper is identical with the African Yaws, which is indigenous among the negro races, that it spread to the Moors and Jews in Northern Africa, and was thence conveyed by them into Spain and Portugal ages before it spread into France and Italy, and there became epidemic, will account for the first appearance of the distemper in the cities of the Iberian peninsula not having been mentioned, inasmuch as it had become there a well-known malady for ages before the end of the 15th century.

35. ii. DESCRIPTION OF PRIMARY SYPHILITIC ULCERS.—These, usually termed *chancre*s, are caused by the application of the syphilitic virus, to any part—mucous or cutaneous: to the former when entire or otherwise, to the latter also when entire, but much more readily when wounded or abraded. Their common *seat* is the genitals; in men, most frequently on the inner surface of the prepuce, or between the prepuce and corona glandis, and especially in the angle by the side of the frænum. "The time at which venereal sores appear is said to be from the third to the tenth day after infection; but it is more probable, as RICORD observes, that the syphilitic virus operates progressively from the first moment of its application, but that the ulcer is fully formed by the fifth day, although it may not be perceived till later." (DRUITT.) The average *duration* of a

syphilitic ulcer produced by inoculation is, according to WALLACE, twenty-five days.

36. Primary syphilitic ulcers present several varieties, which have been arranged by Mr. HENRY LEE under the following heads: 1st. The indurated or Hunterian chancre—a slow, torpid ulcer, encircled by adhesive inflammation; 2d. The non-indurated, or pustulous, ulcer, marked by early and free suppuration; 3d. The phagedænic or ulcerative; and, 4th. The sloughing; 5th. To these I may add, Urethral chancre.

37. 1st. *The indurated or Hunterian chancre* "is generally found on the common integument, or on the glans penis. It may begin either as a pimple, or as a patch of excoriation which heals up, leaving the centre ulcerous." When this ulcer is produced by inoculation, in order to observe accurately its progress, M. RICORD states, "that the puncture reddens during the first twenty-four hours; that in the second and third days it swells slightly, and becomes a pimple, surrounded by a red areola; from the third to the fourth day the cuticle is raised into a vesicle by a turbid fluid, with a black spot on its summit caused by the dried blood of the puncture; from the fourth to the fifth day the morbid fluid increases, and becomes purulent, the vesicle becoming a pustule with a depressed summit. The areola, which had increased, now begins to fade; but the subjacent tissue becomes infiltrated and hardened with lymph." After the sixth day, "if the cuticle and the dried pus which adheres to it be removed, there is found an ulcer, resting on a hardened base; its depth equal to the whole thickness of the true skin, its edges seeming as if cleanly cut out by a punch—its surface covered with a grayish pultaceous matter, and its margin hard, elevated, and of a reddish-brown or violet colour. The ulcer feels to the finger like a little cup of cartilage set in the flesh."

38. 2d. *The suppurating or non-indurated chancre* has been divided into four stages. It is first a small itching pimple or pustule, and displays when it bursts, secondly, a foul yellowish or tawny sore, with slight swelling and redness, and spreading circularly; it may or may not be covered at first with a dirty brown scab. "In the third stage it throws out indolent fungous granulations (and in this stage is sometimes called the *raised ulcer* of the prepuce), and is usually stationary for a little time, after it has ceased to ulcerate and before it begins to heal. In the fourth stage it slowly heals; cicatrization being preceded by a narrow vascular line. If the ulcer be seated near the frænum, it is sure to perforate it."

39. 3dly. *Phagedænic chancre*s are very painful and rapid in their progress. Their surface is yellow, and dotted with red streaks; their shape irregular, their edges undermined or irregular, and the discharge from them profuse, thin, and sanious. The surrounding margin usually appears puffy or œdematous, generally presenting a low grade of vitality, but sometimes it is firm, and vividly red. These ulcers occasionally eat deeply into the substance of the penis, or undermine the skin extensively; but they generally spread much more widely than deeply, and hence they have been called *serpiginous*. Sometimes these sores are more irritable than phagedænic, being acutely painful, discharging a thin ichor, having a raised surface of yellowish exudation, but not spreading much although obstinately refusing to heal.

40. 4th. *Sloughing chancre*s are most frequently observed in the prepuce and integuments. Other chancres, however, presenting the simple states of inflammation observed in the second variety, may be changed into a gangrenous or sloughing state by local irritation, excessive horse-exercise, by excessive debauchery, intoxication, or whatever depresses or exhausts vital force.

41. 5th. *Urethral Chancre*.—The secondary syphilitic symptoms which were formerly attributed to gonorrhœa have been satisfactorily proved by RICORD, but very long believed to proceed from a chancre in the urethra, and the distinct natures of the two venereal diseases thereby determined. The existence of chancre in the urethra may be inferred, if, with many of the symptoms of gonorrhœa, the discharge varies much, sometimes being thin, scanty, and bloody, sometimes thick and profuse; and if there be one painful and indurated spot, not far from the opening of the urethra. But the existence of urethral chancre can be certainly proved only by the ulcer being visible at the orifice, or by inoculation with the matter.

42. SYPHILITIC ULCERS IN THE FEMALE may assume the several states described above. They do not commonly cause so much distress as in the male, although there are many exceptions to this rule; but they are always slow in healing, especially when the urine passes over or comes in contact with them. When they are seated high in the vagina, the symptoms produced by them are very equivocal, the discharge not materially differing from that attending other lesions; an examination by the finger or by the speculum being requisite.

43. iii. THE DIAGNOSIS OF PRIMARY SYPHILIS.—Various affections, described under their appropriate heads, may be mistaken for chancre. These are, 1st. *Gonorrhœa externa*, or *balanitis*, consisting of inflammation of the glans and inside of the prepuce, with profuse purulent discharge and excoriation of the cuticle. It may proceed from gonorrhœal infection, or from neglect of cleanliness, and the acrid secretions of the part, or the unhealthy secretions of the female, especially in a person with a long prepuce; 2d. *Minute aphthous-looking points* surrounding the glans; 3d. *Herpes præputialis*; 4th. *Psoriasis præputii*; 5th. *Chronic eczema*, which, however, rarely affects the genitals, unless it be present in other parts; 6th. *Simple excoriations*, from friction or other non-specific causes.

44. It must, however, be admitted that the characters of primary syphilitic affections are not sufficient to enable us to distinguish them with certainty from the above or similar affections arising from ordinary causes; and that the several varieties of primary syphilis now described afford us no sure ground for practical distinctions between each other. The only circumstance in which all writers, from Astruc to the present day, agree, is that ulcers of an obstinate nature, attended or followed by induration, are those most likely to be followed by constitutional disease. That the indurated chancre alone is characteristic of genuine syphilis, according to HUNTER, CARMICHAEL, and EVANS, cannot now be credited, and would confine syphilis within very narrow primary limits; for the genuine Hunterian chancre is now extremely rare. Nevertheless, Mr. HENRY LEE and Dr. DRUITT, although they

divide primary syphilitic ulcers into four varieties (§ 36), state that it seems almost certain that it is only after the *Hunterian variety* that constitutional symptoms are to be dreaded, or preventive treatment required; and that sores of the suppurative, ulcerative, and sloughing varieties, and those attended by suppurating bubo, do not, as a general rule, affect the constitution.

45. On this fundamental subject, Dr. COLLES, a most experienced and enlightened surgeon, makes the following remarks: "Although every surgeon must admit that Mr. Hunter's description of a chancre is correct, and drawn from nature, still I believe few will confine this term, or that of primary venereal sore, to those ulcers only which answer to this description. As the result of long, attentive, and anxious observation, I should say that primary venereal ulcers present an almost endless variety of character. I would define a primary venereal ulcer to be one which is remarkably slow in yielding to ordinary, mild, local treatment; but which is curable by mercury, and which, if not so cured, is likely to be followed, in two or three months, by secondary symptoms, which again are also curable by mercury. If, then, there be, as I affirm there is, an almost endless variety in chancres, how can we decide on the nature of primary ulcers, so as to pronounce some to be syphilitic, and others to be mere common sores, or simple excoriations? I reply, that we are to be guided in our decision by observing, first, that many of these suspicious ulcerations cannot be referred to any class of common ulcers, as they strikingly differ from them; and, secondly, by attending to the course which these take, when not interfered with by any stimulant or caustic application, and when treated only with some mild ointment or cold water. If, under these circumstances, we find that, after eight or ten days, such ulcers show no disposition to heal, and if at the same time there be a total absence of any cause, such as defect in the general health, to account for this obstinate condition of the local disease, we may then pronounce them to be syphilitic." (*Op. cit.*, p. 75.)

46. *The constitutional effects* of syphilitic infection are even still more variable and uncertain in their characters than the primary. It is manifest that *bubo* has been considered by many, and more especially by M. BOYER, of too great importance, for it is certainly not a diagnostic of genuine syphilis, nor is it a secondary symptom, but merely a local consequence of the primary sore—the effect of irritation, or of the virus conveyed to the inguinal glands, by the absorbents from the local sore, no constitutional affection often supervening when it suppurates freely. When a patient has a syphilitic sore which has not been destroyed within five days, he is liable afterward to these effects which will hereafter be described as *secondary* and *tertiary syphilis*. Yet, according to Mr. HENRY LEE and Dr. DRUITT, it seems almost certain that it is chiefly after the Hunterian variety that these effects are to be dreaded, and their preventive treatment is required; and that the suppurative, ulcerative, and sloughing varieties, and those attended with suppurating buboes, do not, as a general rule, inflit secondary disease. A developed Hunterian chancre, or its cicatrix if hard or red, like the vaccine vesicle, affects the constitution, "so that if it be cut out or destroyed, the wound will assume the same character, and require the same consti-

tutional treatment, as if the malady had not been interfered with." It has also been recently shown that repeated syphilitic infection begets a protection against fresh attacks; and that the production of additional suppurating syphilitic sores not only does not confer any fresh liability to secondary symptoms, but seems to diminish that which exists already. Hence it has been proposed, as will be shown in the sequel, to inoculate syphilitic and other persons with syphilitic matter, or to *syphilize* them—in order to prevent and to cure this distemper—a subject which will be noticed in the sequel.

47. *The marked differences presented by the primary sores and the secondary symptoms of syphilis*, not only soon after the epidemic appearance of the distemper in Europe, but also during its subsequent prevalence, and in modern times, have been variously explained. Mr. CARMICHAEL believed that there were several distinct species of venereal poisons, each of which produced a specific primary sore and a specific train of secondary symptoms; that the Hunterian chancre, for example, was followed by an exaeated ulcer of the tonsils, sealy eruptions on the skin, nodes, &c. But the history of the malady, the diversified symptoms which result from either form of primary sore, and various other considerations, warrant a belief only in one specific virus or poison, which manifests itself both primarily and constitutionally in varied forms, according to the circumstances of infection—to the intensity of the primary morbid action, to the tissue with which the virus is brought in contact, and to the temperament, habit of body, diathesis, and susceptibility of the person infected. Hence arise different modifications or even varieties of the distemper, all resulting from one specific morbid poison. Thus they pass into each other in every phase or grade, without being originally or specifically distinct; and hence the one form or variety may prevail in different countries and races, and even in different ages, and under different influences, and yet give rise to another variety either as to form or intensity, when it infects different races, diatheses, and constitutions. Even in the same country and race, the circumstances and habits of the infected, especially mental and physical distress, prolonged fatigue and exhaustion, debauchery, frequent excesses and intoxication, neglect of cleanliness, &c., will occasion a much more intense and intractable disease, than in persons differently circumstanced. It was most probably owing to these influences that the disease was so severe even in its primary symptoms among our troops during the campaigns in Portugal and Spain, and so mild among the natives. Owing probably to the difference in race, it presented to my own observation in Africa different modifications or forms and grades of intensity among the negroes, from those more usually observed in the white race. As to this topic, however, I would suggest a further, and more precise and extended observation, than I was enabled to make. There can be no doubt that in this country various forms of constitutional affection may proceed from the same kind of primary sore.

47\*. III. *SYPHILITIC BUBO*.—Inflamed and enlarged lymphatic glands, consequent upon a venereal ulcer, arise from the virus contained in, or secreted by this ulcer or chancre. This affection of the inguinal glands may arise from the irritation of, or absorption from, gonorrhœal inflamma-

tion of the urethra; but it is not so frequent, nor so severe as when it is caused by chancre. Syphilitic bubo cannot be viewed as an indication of the existence, or even of the commencement, of the secondary or constitutional disease; for the affection of the glands may even, according to the more recent occurrences of the disease, be the means of preventing the constitutional contamination. This, however, was not the case in the earlier histories of the distemper, and more especially after the epidemic prevalences of the disease in the end of the 15th, and during the 16th century—a. *The forms and diagnosis of bubo* have been correctly and succinctly given as follows by Dr. DUVITT: 1st. *Bubo of the penis* is an inflammation of a lymphatic in the penis, which may be felt like a cord under the integuments, and which passes into abscess in some part of its course. 2d. *Acute bubo* in the groin generally affects one gland, and pursues the course of an acute abscess. The cellular tissue surrounding the gland is the usual seat of suppuration, but there may be also a small abscess in the centre of the gland, caused by the transmission of the poisonous matter, and the pus of this latter is alone capable of producing a chancre by inoculation. 2d. *Chronic or indolent bubo* commonly affects more than one gland. It occurs in weak or scrofulous habits, and especially in persons injured by the improper use of mercury. The glands enlarge slowly, suppuration is protracted and imperfect, and commences at several points. The skin is long in inflaming, and on becoming so a large tract assumes a dusky bluish tint; the matter extends, and at last large portions of skin perish by ulceration, leaving an extensive sore, that may be months in healing.

48. b. *The diagnosis of syphilitic bubo* requires attention. If one gland only, and that above Poupart's ligament, be affected, it is most probably caused by chancre on the penis, provided there be or has been one. "But if many glands are swollen, and they are below the level of Poupart's ligament, the swelling is probably caused by some irritation about the foot (or extremity). But the only sure diagnosis of a syphilitic bubo is that, if the matter taken from it be inoculated, it will produce a chancre; or that the sore produced by opening the bubo presents the elevated edges and copper-coloured margin of a chancre." As every bubo is attended by suppuration of the surrounding cellular tissue, the matter taken when first opened may not cause chancre by inoculation. There is no certain proof of a bubo being syphilitic unless preceded by chancre, unless a chancre can be produced by inoculation of the discharge, or unless decided secondary symptoms supervene.

49. IV. *SECONDARY SYPHILIS*.—Constitutional syphilis may occur from a fortnight to three or four months after the primary symptoms. The usual time is five or six or seven weeks. Early in the history of syphilis in Europe, the constitutional affection was much more early than the shortest time now named, and was not unfrequently the first produced, owing to the readiness with which the contagious principle was imparted and imbibed. Before the appearance of secondary symptoms, the constitution betrays its infection by a variety of *premonitory symptoms*—by a dispirited and even wan expression, by want of appetite and sleep; by heaviness of the eyes, rheumatic pains, especially during the night, and pal-

lor and loss of flesh ; and, lastly, by a slight eruptive fever usually of an inflammatory type. Upon these, after a short but variable period, the secondary symptoms supervene, sore throat generally accompanying this fever or soon following it.

50. *The symptoms premonitory* of the secondary or constitutional disease are sufficient evidence of the infection of the body by the primary disease, although those alterations usually termed secondary are not yet developed. The dull, earthy hue of the surface, the loss of bodily health and mental vigour ; the dryness of the hair, and loss of its smoothness and glossiness, and the giddiness, headache, uneasiness about the neck, or supra-orbital pain, usually on one side, and when the body is recumbent, are among the earliest indications of this infection. On these supervene pains about the joints ; lassitude of the limbs ; enlargement of the posterior cervical glands ; loss of the tone, fulness and strength of the pulse ; more or less anæmia, and falling out of the hair. The loss of hair indicates an inveterate form of disease, and is often attributed by patients to the use of mercury ; but this mineral will not cause *alopecia*, but syphilis will. These symptoms, although not generally recognised as secondary, are so nevertheless, and, if not arrested by treatment, will soon be followed by those which are more generally described as such.

51. 1. *SYPHILITIC ERUPTIONS.*—*The secondary effects of syphilis* are ultimately developed either on the skin or mucous membrane, especially of the throat, or on both.—A. The earliest of these to appear is an *exanthematous* or *erythematous eruption*, which may be either attended by fever, as stated above (§ 49), or entirely independent of fever. This eruption may occur either during the existence of the primary symptoms, or a few weeks after their disappearance. It sometimes assumes the appearance of either measles or scarlatina, and at its commencement is usually of a rose-colour, the surrounding skin being of an unhealthy or dusky hue. The redness disappears on pressure, but returns immediately when pressure is removed. The surface of the body may be covered at once, but more frequently in succession, by this eruption, which soon loses its rosy hue, and daily becomes more and more dusky, until it assumes a coppery and more permanent tint. It is generally unattended by either heat or itching. It generally fades away for a while, and then reappears ; and it may thus proceed, with interruptions, for two, six, or twelve months, but after a year or two it entirely dies away. In half the cases the eruption remains unnoticed, and it very often fades away without the patient being aware that it ever had any existence ; but some time after another and a deeper eruption makes its appearance. This state of the eruption may be mistaken for pityriasis, or this latter for syphilis ; but the history of the case, the appearance of the eruption, the absence of itching, and the impaired health of the patient, will indicate its syphilitic nature.

52. B. A more developed form of syphilitic eruption may appear as *papulae*, of various sizes, or as *psoriasis*, in which the skin is raised in copper-coloured blotches, covered by *scales* of hypertrophied cuticle. These eruptions are succeeded merely by exfoliations of the cuticle or thin superficial scabs. An aggravated state of the foregoing begins with an eruption of copper-coloured blotches, which become covered with *scales* of en-

larged cuticle, and form *syphilitic lepra*. These scales are succeeded by thin scabs, and these, on falling off, leave shallow ulcers with copper-coloured edges.

53. C. *Vesicular eruptions*, often assuming the form of *rupia*, may occur, appearing at first as large flattened bullæ, filled with serum, passing into a purulent state, and finally drying into thick scabs, under which the skin is ulcerated. The ulcers spread under the scabs, and, owing to the successive additions of the dried matter as they extend, they become remarkably thick, conical, and resemble limpet shells. The eruption may be distinctly *pustular*, constituting *syphilitic ecchyma*, the pustules being large and prominent, leading to ulcers, with a copper-coloured base.

54. D. *Tubercular eruptions*, broad, reddish, or copper-coloured, appear on the face, most frequently at the ælæ of the nose, or on the cheeks. They suppurate slowly, and are succeeded by deep irregular ulcers, terminating in puckered cicatrices. This eruption, in Dr. DUNN'S opinion, more properly belongs to the class of tertiary symptoms, in which mercury is almost inadmissible. This eruption usually appears a very considerable time from the primary symptoms in persons of weak constitution, or who have been broken down by privation, dissipation, or unavailing courses of mercury ; it is consequently an unfavourable form of the disease. "A patch of this kind of unhealthy inflammation is apt to form on the tongue, and after a time an abscess breaks, disclosing a ragged excavation, filled with orange-coloured sloughs, and exuding a copious fetid discharge. If it occur on the palate, a probe will detect bare exfoliated bone, which rapidly perishes, and leaves a hideous chasm."

55. E. *Mucous Tubercles, Condylomata*—*Tubercule muqueux, Pustule Plate*, consist of raised patches of skin, with a red and moist surface, like mucous membrane. They exude a thin, acrid, and offensive discharge. They are most frequently situated in the vicinity of the genitals, or in any other place where two surfaces of skin come in contact, presenting an excoriated appearance. They constitute a peculiar syphilitic eruption, and are undoubtedly capable of producing constitutional syphilis, generally with a similar eruption, in healthy persons. Indeed such a result may follow the tubercular or even the pustular forms of secondary syphilis in certain favourable circumstances. (*The several forms of syphilitic eruption are more fully described in the several articles devoted to diseases of the skin.*)

56. Venereal eruptions are not severally characteristic of any distinct form of syphilis, primary or constitutional. Dr. COLLES states, 1st. That he has not been able to trace back particular forms of eruption, to particular forms of primary ulcer. 2d. He has not unfrequently observed varieties of eruption existing together in the same person. 3d. After the removal of the first eruption by mercury or other means, the second crop will often prove of a different kind ; and, 4th. Any form of eruption may be converted, by injudicious treatment, as the excessive use of mercury in bad habits, into one which is most obstinate and severe. This opinion agrees with those of HENNEN, OESTERLAN, S. COOPER, BACOT, and others. Mr. BABINGTON considers the variety of venereal eruptions to be so great as to baffle description. He, however, arranges the more distinct forms under the heads of *Tubercles*,

*Lichens, Psoriasis and Lepra, and Rupia.* The most important practical point, which many writers connect with these distinctions into form of eruption, is, that rupia and ecthyma are met with in a very dangerous general depression of health, requiring the greatest care.

57. *F. The diagnosis of secondary eruptions* is of great importance—is sometimes very easy, and occasionally very difficult. In all cases the previous history of the patient should be inquired into. It is not only necessary to ascertain whether or no a chancre has existed, but also the time when it occurred, its situation, and its character. If no chancre, but gonorrhœa only, in male or female, preceded the eruptions, it should be recollected that chancre may have escaped the patient's notice, or may have existed in the urethra of the male, or in the vagina or cervix uteri. In these cases caution and farther observation are required. If sores are admitted, their characters, especially as regards induration, are of importance.\* A knowledge, likewise, of the existence of suppurating bubo may be useful, for indurated chancre is rarely attended by suppurating swelling in the groin; and, lastly, the existence of any traces of indurated chancre or bubo ought to be ascertained, the denial of the patient not being sufficient.

58. As respects the eruption, M. RICORD remarks that one of the most important characters of it is a total absence of pruritus, whereas itching is a very frequent symptom of the other kinds of eruption. When, however, the syphilitic eruption affects naturally pruriginous regions, as the anus, the genito-crural fold, there may be considerable itching, owing to the irritating nature of the secretion. Syphilitic eruptions are generally apyretic and indolent, involving in a short time the whole body, generally by successive instalments. They spread indiscriminately to all parts, and do not affect the face in preference to other parts. They emit no smell, unless there be an exudation of fluid or suppuration. "There is nothing specific in the smell, nor in the colour mentioned by SWEDIAUR, nor the ham-like hue spoken of by FALLOPIUS, which latter has been, with reason, looked upon as an important sign, and an absolute and constant character." Secondary eruptions generally present rounded and well-defined patches, the colour of which may be

more or less deep in their centres. They have very little tendency to suppuration; and when matter does form, it is generally small in quantity and unhealthy in character. The eruptions which do not suppurate, generally disappear in time by resolution or desquamation. The scales in these cases are less brilliant and thinner, dry more quickly, and more frequently furfuraceous than in non-specific affections, and the scales sometimes fall off in large shell-like pieces. The crusts sometimes accumulate in successive layers, as in rupia. When, by the falling of the crust, the ulceration underneath becomes apparent, it generally is rounded, its fundus grayish and pul-taceous, is surrounded by a darkish areola, with a certain induration in the margins. Phagedæna of these ulcerations is rare; but when it does happen, it sometimes extends rapidly. Secondary syphilitic ulcers are preceded either by some eruption, as ecthyma, rupia, papule, or tubercles: they rarely follow vesicles or psyracous pustules. RICORD agrees with HUNTER in considering the diagnosis of secondary symptoms as most difficult; for "there is hardly any disorder that has more diseases resembling it in all its forms than the venereal disease."\*

59. *G. Secondary affections of the scalp—Alopecia syphilitica*—is among the earliest constitutional disorders consequent upon syphilis. It commences with a slight itching, tenderness or soreness of the scalp, attended by rheumatic pains. On examination, no trace of eruption can be detected; but if the patient have suffered within four or eight weeks from chancre, or if any induration remain in its situation, the tenderness of the scalp will soon be followed by the loss of hair and some one of the affections of the skin, throat, &c. The alopecia commences very gradually. The hair at first becomes dry and crisp, loses its glossy appearance, breaks readily, a brush or comb causing great pain. The hair is often seen broken off close to the scalp, and patches of baldness, or approaching to it, are found here and there. At a more advanced stage the hair comes away with the bulbs in considerable quantity. Pityriasis now becomes troublesome; and various points of the scalp assume a rosy hue; the rest of the skin generally having a yellowish, unhealthy appearance. Slight febrile symptoms set in, attended often with rose-coloured spots on the abdomen. The patient now frequently complains of rheumatic pains in the joints, with loss of appetite and debility. The loss of hair requires immediate attention, especially when caused by syphilis, as it may be very considerable in a short time, and its growth very uncertain. It should, however, be remarked that if the hair does not fall out at the commencement, it is not very frequently lost in the latter stages of constitutional syphilis.

60. At a more advanced stage, a papular affection of the scalp, commencing with little rose-

\* DR. MCCARTHY says, "In 123 cases of secondary symptoms, indurated chancre had preceded the eruptions 118 times, and been recognised in the hospital, or the patient recollected having felt it. In one case only the patient could recollect that a clap only had preceded the condylomata which we observed on the patient; but this clap was attended, he told us, with a bloody discharge, which occurred seven months previous to his admission into hospital. In 4 cases we were unable to obtain accurate recollections on the subject of induration."

"The examination of these 123 cases clearly proved to us, in consequence of the frequent unexpected situation of the primary sore, the reason why we daily meet with cases which give reason to suppose that secondary symptoms may arise spontaneously. In 6 cases the sore was seated in the urethra, when inoculation enabled us to recognise it three times; in other cases the disease, at first concealed from view, ultimately appeared as a urethral chancre at the meatus. Four times at the anus, once in the nostril, once on the chin, once on the lip. Suppose we take these 123 patients, and compare those primary symptoms, for the purpose of attempting to discover some one character which appears sufficiently often to enable us to draw a deduction from it, we find that in one and all the inguinal glands have been observed enlarged, but suppuration took place only twice, and in these the buboes had a scrofulous appearance, and it was not possible by inoculation to obtain the specific pustule." (Note from Aeron's ep. cit., p. 488.)

[\* For the best description of the *syphilita, or syphilitic eruptions*, the reader may consult the American edition of VIDAL "On Venereal Diseases," with colored plates, translated by GEORGE C. BLACKMAN, M.D., 8vo, p. 499. New York: Samuel S. and William Wood, 1854. In this, the ablest work on this class of diseases hitherto published, the different varieties, including the *exanthematous, papular, squamous, vesicular, bullous, pustular, and tubercular*, are described at great length, and accurately represented by coloured engravings. We feel tempted to give a synopsis of these varieties, but the work is so accessible, and so well known to the American profession, that it is unnecessary.]

coloured elevations, attended by itching, is observed. These papulæ, or *liehens*, increase in number, slight pearly-white scales form on their apices, which fall away and are replaced by others. The hair is scurfy, and the papulæ or elevations, at first the size of millet-seeds, become large and assume the form of *lepra* or *psoriasis*. When the scales are removed, the skin looks like a recently-blistered surface, and exudes a small quantity of thin pellucid fluid; or it is quite dry. In particular situations, especially behind the ears, in the folds of the neck of stout persons, or those inattentive to cleanliness, those places instead of becoming scaly remain moist, the oozing from them excoriating the surrounding parts, and developing mucous tubercle or condyloma. As the disease of the scalp advances the papulæ or lichen pass into an impetiginous or an eczematous state. In still more advanced stages, ulcerations of a very intractable character, forming tertiary symptoms, form in the spots of impetigo or eczema; and tumours as large as horse-beans form in the scalp, at first unattended by pain or redness. Fluctuation may be detected in them after some time, and when punctured a thin, serous, straw-coloured fluid exudes. If left alone they become painful and red, ulcerate, exposure of the bone ultimately following, and even necrosis, which are now chiefly seen in pathological collections, and but rarely in practice in the present day.

61. *H. Syphilitic Onychia*.—The venereal affections of the skin or scalp may be extended to the nails. In these cases the matrix suffers, and the nail grows thick and nodulated, closely resembling the changes which take place in it from inveterate psoriasis. There is a great similarity between onychia and alopecia. They both depend upon the constitutional infection interfering with the formation or nutrition of these cuticular appendages.

62. ii. *SYPHILITIC AFFECTIONS OF MUCOUS SURFACES*.—*A. Syphilitic Affections of the Throat*.—*a. The mildest affection* of this kind is a superficial excoriation of the mucous membrane, most frequently of the tonsils, but not unfrequently also of some other parts of the fauces or mouth, corresponding to psoriasis on the skin. The affected parts are slightly swollen and sore, afterward red and raw, or covered with a whitish exudation, or with a patch of thickened epithelium. If the disease proceed it will generally be followed by superficial ulceration.

63. *b. An excavated ulcer* may follow the foregoing, or may be first to come before the physician, although it may have been a consecutive lesion of the parts. This ulcer appears as if a piece had been scooped out of the tonsil. Its surface is foul or yellow, its edges raised and ragged, and swollen. It occasions much less inconvenience than its appearance might indicate; and there is very little constitutional disturbance from it, unless it be attended by eruption. As the lesion advances, or swelling increases, the patient's speech becomes guttural, and he often complains of pain shooting to the ears, and of partial deafness.

64. *c. Sloughing ulcer* begins as a small aphthous spot which rapidly ulcerates, and is attended with great pain and fever. "The surface of the ulcer is covered with an ashy slough, and the surrounding membrane is dark, livid, and swollen. The lingual artery may be opened by the spread

of the ulceration, and the patient may die of hæmorrhage, unless the common carotid is tied." (Druitt, p. 187.) In some instances, especially when mercury has been given in large quantities for primary symptoms, the affection of the throat comes on notwithstanding, and assumes a red and sloughy appearance; a piece of the tonsil appears as if punched out, and the ulcers rapidly extend in size and depth.

65. The *situation* of the ulcerations, most frequently of the excavated, is commonly on the tonsils, on the sides of the tongue, on the upper surface, or on the under surface close to the frænum. Sometimes they are met with on the dorsum of the tongue, here assuming an elevated character, like the condylomata around the anus. They occasionally attack the palate, pharynx, and more rarely in the posterior and lower part of the pharynx, in which latter situation it occurred in a patient many years ago under my care, ulceration also having extended to the larynx and terminated fatally. Ulcers also form at the corners of the mouth, where they may form scabs, or are liable to bleed when the mouth is fully opened.

66. *B. Syphilitic ulcerations of the nose and palate* commence with inflammation and ulceration of the mucous membrane covering the parts, similar to those of the throat. The ulcerations may proceed until they denude the periosteum, and afterward produce exfoliation of the bones and profuse fetid discharge, and ultimately very marked deformity. Ulceration of the nose generally begins with ozæna, or with a sense of pain, heat, dryness, and snuffling. But the bones of the nose may become otherwise attacked, as shown in the sequel (§ 75).

67. *C. Syphilitic ulceration of the larynx* is chiefly a consequence of the extension of ulceration from the palate or pharynx. It is characterized by tenderness, slight pain or uneasiness referred to the larynx, by huskiness of voice, followed by a low whispering, or loss of voice; by suffocative cough, and by expectoration of a sanguineo-puriform matter. There is great loss of strength and flesh; and life is often terminated by suffocation.

68. *D. Secondary Affections of the Eyelids and Eyes*.—Not only may inflammation of the eye be consequent upon gonorrhœa (see *art. EYES, gonorrhœal inflammation*, § 56, *et seq.*), but eruptions and affections of the eyelids and of the eyes themselves, chiefly in the form of iritis, may appear in the course of secondary or constitutional syphilis. These eruptions often appear on the external surface and on the ciliary margins of the lids. In some instances the corners of the eyelids have a cracked, scaly appearance, resembling a similar alteration more frequently occurring at the angles of the mouth, and, as in this latter state the eruption is connected with syphilitic affections of either the skin or of the mucous membrane, of the throat, &c., or of both; and it may appear in any period of the progress of these affections. In some cases the conjunctiva is also either partially or extensively implicated. *Syphilitic iritis* is not unfrequent; and is fully considered in the article on *the diseases of the eye* (§ 132, *et seq.*), to which I must refer the reader.

69. iii. *TERTIARY SYPHILITIC DISEASES*.—Certain constitutional effects of syphilis, which more frequently are consecutive of several of those

already mentioned, than associated with them—although such associations, especially in the advanced course of the latter, are often observed—have been classed as *tertiary symptoms* of the disease. They may, however, occur after the removal of the secondary forms of the distemper, or independently of these, and at a remote period from the primary symptoms. Under the term *tertiary symptoms* have been arranged *nodes*, *inflammation of the periosteum*, *exostosis*, *caries of the bones*, *tubercles of the sub-cutaneous and sub-mucous tissues*, *disease of the testes* consequent upon primary or secondary syphilitic disease. These affections were generally classed with those secondary symptoms already noticed. JOHN HUNTER first distinguished them by designating them the “*Symptoms of the second period of constitutional syphilis*,” a designation which many will agree with me in considering as more appropriate than that imposed on them by M. RICORD.

70. Though *tertiary symptoms* generally depend upon chancre, or, in rare cases, upon infection by a secondary disease, they follow the primary symptoms after a much longer interval, and they are seated in other and more deeply-seated structures than the secondary. They affect chiefly the sub-mucous and sub-cutaneous cellular tissue; the structure of the bones; the fibrous structures, especially the periosteum; the joints; the testes, and lymphatic system. The syphilitic poison may even develop disease of the liver, lungs, brain, and heart. Tertiary affections cannot be transmitted from parent to child—are not hereditary; but they are undoubtedly capable of producing a scrofulous diathesis in the offspring.

71. *A. Course.*—In the more usual course of the disease, tertiary symptoms do not supervene until six, seven, or nine months from the primary, and in some they may be delayed for several, or even as many years. Although these symptoms may be separated with propriety from the secondary, yet it will very frequently be difficult to draw the line of demarcation between them. They may be both so associated, or the one class may pass so insensibly into the other as not to admit of an inference as to the predominance of the one set of symptoms over the other. In the natural course of syphilis the tertiary form very frequently thus appears during the existence of the secondary, in the same way as the latter may come on during that of the primary. Under other circumstances, as from treatment, careful regimen, &c., the secondary symptoms may have successfully disappeared and returned, and ultimately the tertiary have supervened; and even, although in rare instances, an indurated chancre may have existed, and been apparently cured, yet, after a very considerable lapse of time, tertiary symptoms may appear generally from the influence of causes hereafter to be noticed (§ 109, *et seq.*), at first in a slight form, but with increasing severity, notwithstanding the non-existence of secondary symptoms between the primary and tertiary. During the course of tertiary affections, various *complications* may be developed, not only by the syphilitic poison, but also aided by treatment, by pre-existing tendency to visceral or other diseases; by the causes, influences, and circumstances to which the patient may have been exposed, and by climate, race, occupation, &c.

72. *B. Syphilitic affections of the testes* are generally among the earliest of tertiary symptoms to appear, and may occur during the existence of

the secondary. They may, however, supervene in five or six months, or not until as many years, from the primary infection. They may appear either alone, or attended by pains in the bones, exostoses, or gummatæ; but they are of rare occurrence in the present state of the distemper. ASTRUC first, and HUNTER, Sir A. COOPER and DUPUYTREN, subsequently, made the distinction between diseased testicle consequent upon syphilis and that following gonorrhœa. Syphilitic disease of the testes may commence in one and extend to both, or it may begin in both at once. Excepting slight nocturnal pains in the loins in some cases, the affection often reaches a considerable height before it is noticed. When the patient's attention is attracted by it, the testes are found heavy, hard, and generally much increased in size, although not always. The disease may run its course without much uneasiness, and hence be neglected, and organic lesions may supervene which cannot be removed. The erections, however, and the venereal desire become, on the full development of the disease, less frequent, and the seminal discharge is diminished. If the disease continue, or be neglected, the testes decrease in size, and ultimately may become atrophied, and may even disappear nearly or altogether. These changes are extremely slow, and may continue for several months or even years before the organs are entirely lost. A full description of them will be found in the works of M. RICORD and Mr. ACTON.

73. *C. Small tumours* are sometimes formed in the *scrotum*, and are described as *tubercles*, or *gummatæ*, either in connexion with disease of the testes or independently of it. They occur as a tertiary symptom in the deep layers of the scrotum, and sometimes implicate the testes, or are mistaken for affections of these organs. They never appear before the fifth or sixth month from infection; but they may occur after many years. They mostly appear as small elastic tumours, and feel as if they were filled with a gummy matter. As they grow they become painful, inflamed, and the skin covering them softens and ulcerates, and a deep ulcer follows a copious puriform discharge. The edges of the sore are undermined, and the adjoining parts are involved in the destruction.\*

[\* See paper by JOHN WATSON (in *New York Journal of Medicine* for November, 1845), entitled “Further Observations on some of the more obscure and remote Effects of Syphilis;” also, in same journal for July, 1843, Dr. W. was one of the first, if not the first, in this country to show that the venereal disease in its progress through the system may affect the *brain* and its *meninges*, the *œsophagus*, the *bronchial tubes*, and the *testes*; and that it may simulate other diseases, as *pulmonary phthisis*, and diseases of the *digestive organs*, *liver*, &c. Among the cervical ganglia he shows that it may simulate *strumous adenitis*, and in the lower extremities *elephantiasis*, while it occasionally involves the *rectum* and *prostate gland*. He also offers some very original and interesting remarks on “the rarity of secondary syphilis after sloughy primary sores; on the frequent and early occurrence of superficial necrosis in connexion with nodes; on the co-existence of syphilis with other constitutional diseases; and on mercurial cachexia, as liable to be mistaken for the remote effects of syphilis.” With regard to the syphilitic affection of the testicle, from various examinations, Dr. WATSON concludes that the primary seat of the affection is in the fibrous envelope forming the proper capsule of the testis, which occasionally becomes enormously thickened, while the proper tissue of the testis remains healthy. The tubuli seminiferi, with their continuous vessels of the epididymis, were atrophied, pale, and immersed in serous effusion. In one case there was a deposit of a large yellow mass, irregular in shape, broadest in front, and apparently connected with the fibrous en-

74. *D. Syphilitic disease of the periosteum and bones* generally commences with tenderness in the situation of the more exposed and superficial bones, especially in the bones of the nose, in the tibia, ulna, cranial bones, clavicles, &c. The tenderness and pain become aggravated in the evening, last all night, but cease altogether or abate during the day. The pain is followed by oblong swellings or *nodes*, caused by the inflammation of the periosteum, and by the infiltration of lymph and serum. These swellings are tender, and the skin over them is at first pale and moveable. They present to the touch a doughy character, or an obscure sense of fluctuation. Dr. Druitt remarks that "if the disease is arrested at this stage, it causes merely a superficial deposit of rough porous bone, from the organization of the lymph effused; or else consolidation of the bone itself, through deposition of fresh osseous matter into its cancelli. If the disease proceed one step farther, a quantity of glairy serum is effused between the periosteum and bone, producing an exquisitely painful fluctuating tumour. If it advance still farther, the bone becomes carious; matter forms between it and the periosteum; extensive exfoliations ensue; the patient suffers severely from the pain and discharge;" and if the disease be seated in the cranium or os frontis—*corona Veneris*—death may ensue from extension of disease to the dura mater, or from protrusion of the brain through the eroded apertures in the skull. Such extreme cases are now very rare, but they were common enough many years ago, and when it was supposed that mercury given in excess was the only cure for the distemper.

75. *E. Disease of the bones of the nose* is often among the earliest of the tertiary symptoms, but it is of only occasional occurrence, and sometimes not until an advanced period. The nose may become diseased, as stated above (§ 66), from ulceration of the mucous membrane; but the formation of internal nodes on the palate, vomer, ethmoid, and bones forming the bridge of the nose, may cause these bones to be carious, and probably the spongy structure of these bones may contribute to this even so quickly as it is sometimes observed. In rare cases these bones are nearly destroyed before the nature of the disease becomes apparent. When caries of the os frontis near the root of the nose takes place, the disease may extend to the ethmoid bone, and produce the worst effects. The existence of a deep-seated pain in the palate, and at or near the root of the nose, with or without a fetid discharge, should always be viewed with suspicion, especially if either primary or secondary symptoms have existed at some previous period, although very remote, and apparently altogether removed. *Ozæna* may proceed from scrofula, scurvy, or even from chronic cephalic catarrh; but in 99 cases out of 100 it is the result of syphilis in the circumstances just named.

76. *F. The joints* are not frequently nor so quickly affected as the bones. Large gummy swellings sometimes, however, form around the ankle, knee, and elbow joints, owing to venereal disease; and in rare cases even the joints themselves. In two instances I was consulted

where nearly all these joints were remarkably swollen and diseased, consequently upon other serious syphilitic affections. In a third—that of a late M.P.—amputation of the leg above the knee had been performed by Mr. DALRYMPLE, of Norwich, and the case subsequently came under my care. The small bones of the extremities may also be similarly affected. In venereal diseases of the joints it is difficult to determine, as I have not seen these cases terminate fatally, although they doubtless occasionally do, whether the disease is entirely external to the joint itself, or whether the articulations or the ends of the bones are also implicated by the disease. That the cartilages are sometimes eroded, and even the ends of the bones or their epiphysis also are affected, may be inferred not only from the case for which amputation was performed, but also from what is observed to occur as regards the cartilages and bones of the nose. These local syphilitic diseases—of the bones, joints, &c.—are generally attended by a slow or *syphilitic hectic*, and with the several constitutional phenomena described hereafter as the syphilitic cachexia.

77. *IV. THE SYPHILITIC CACHEXIA.*—It may justly be asked, can syphilis so contaminate the constitution as to give rise to dangerous or even fatal results of a different kind, or in addition to those which have been described above as secondary and tertiary? To this question I cannot hesitate to answer in the affirmative. These results do not often occur in the present day; and even the most severe of the tertiary affections noticed above, although sometimes terminating fatally, have not always this issue. In their most unfavourable results, it is often difficult to say how much may be imputed to treatment. But, irrespective of the more severe and dangerous of the affections already mentioned, states of the system may be induced, attended by marked severity or imminent danger, in which none of these affections had appeared, or, if they have appeared at some previous periods, they had been removed by medical treatment or regimen. This dangerous state of constitution—this the most remote or advanced of the effects of the syphilitic poison—has not been overlooked by previous writers, more especially by Dr. COLLES and M. RICORD.

78. Syphilitic cachexia is generally a consequence of a single constitutional contamination (*such contamination not occurring twice*), and is favoured by the following circumstances: 1st, by an originally weak or bad constitution, by scrofula, scurvy, and a peculiar or vitiated diathesis, previously to the venereal infection; 2d, by the persistence of certain severe syphilitic symptoms; 3d, by an ill-timed or badly-managed treatment, and by neglect of treatment; and, 4th, by causes which tend to lower the vital powers subsequently to infection—such causes, according to my observation, being excessive sexual indulgences, masturbation, exposure to cold and moisture, to the continued influence of malaria, or to noxious exhalations, &c.

79. *The symptoms of syphilitic cachexia* are not always well defined; for they may be associated with certain of those already noticed, or they may appear as the sequelæ of some of the more severe of them, or they occur at periods so remote from them as to occasion grave doubts of their nature and origin. They may, however, be stated to consist chiefly of pallor, sallowness, and anæmia

velope of the testicle, and extending backward in the direction of the corpus Highmorianum. This mass, by pressure, produced atrophy of the tubuli seminiferi. For an excellent account of syphilitic sarcocele, see also VIDAL.]

of the surface, flabbiness of the flesh, emaciation, debility of both body and mind, various anomalous scorbutic or cutaneous appearances, hectic or continued nervous fever, night exacerbations, diarrhœa, sweats, aphonia, and ultimately death, arising from some important internal organ experiencing disorganization, to which it may, previously or subsequently to the venereal infection, have become predisposed. Thus the patient may be cut off by extreme anæmia, by diarrhœa terminating in ulceration of the intestines, by affections of the lungs, &c.

80. Sometimes, after the patient has improved, under treatment for various secondary or tertiary symptoms, in respect both of these symptoms, and of flesh, strength, and appearance, he begins to exhibit a much less favourable aspect. He appears sickly, loses flesh, presents a waxen hue, complains of loss of appetite and strength, of want of sleep, and of night sweats. If any eruptions or other syphilitic symptoms are present, they may disappear, and yet the general constitutional cachexia may long remain, or even become more marked; or, if the local symptoms continue, they may be slowly deteriorated. Thus tubercular eruptions, or pains in the joints and bones, may continue in various grades of severity for some years, while the constitution is slowly wasted, anæmied and visibly contaminated. In some cases the local symptoms, in the course of the general breaking down of the frame, are so changed as hardly to be recognised as venereal—various local or visceral changes, the consequence chiefly of this cachexia, or of the treatment, being developed, and *masking* the venereal affection and its effects. This formerly obtained more remarkably when the treatment by mercury was carried to excess. There can be no doubt, however, that, even independently of this, or of any other treatment, the venereal cachexia may terminate fatally by calling latent tendencies into action, and by developing disease in vital or other internal organs. It may, however, be most manifest in all its indications, even when the local affections are comparatively slight; or, although they have been severe, after they have entirely or almost altogether disappeared. The local affections, as well as the constitutional contamination, are often developed, hastened, delayed, or aggravated by a number of circumstances, influences, and concurring or reinforcing *causes* (§ 115, *et seq.*), to which the patient may have been exposed subsequently to the period of infection. During syphilitic hectic or cachexia, not only may the contingencies now alluded to appear, but there are several others which may also supervene; namely, paralysis, epilepsy, hypochondriasis, melancholia, monomania, and even more or less general insanity. These disorders of the mind are, however, seldom met with even in the advanced states of constitutional syphilis—the intellect being generally but little, or not at all, affected to the last.

81. v. *The diagnosis of constitutional syphilis* is often very difficult, more especially when patients deny that they have had any primary symptoms, or even any suspicious intercourse, or even any sexual intercourse whatever. These last circumstances are, however, very rare, or may even be considered next to impossible. But the rare modes of communicating the distemper, independently of sexual connexion—much more common in former times than now—should not

be forgotten. These modes will be noticed in the sequel (§ 110, *et seq.*). If, however, copper-coloured eruptions, sore throat, loss of hair, enlargement of the glands around the occiput, pains in the joints, periosteum or bones, periosteal nodes on the long and superficial bones, with night pains, a faded, pallid, or waxen and unhealthy look, loss of flesh and strength, be complained of; and more especially if these symptoms follow a somewhat similar succession, and cannot be attributed to locality, diet, regimen, &c., or to any recognised visceral disease, they may be confidently referred to constitutional syphilis. Where, however, neither the above succession of symptoms, nor many of them appear, the difficulty of diagnosis will be much greater, especially if primary symptoms be not admitted; but, if admitted, there can be no doubt of the nature of the disease, although a long period between the existence of the primary symptoms and the appearance of those which are doubtfully secondary may have intervened. It has been stated above that the period to which the supervention of secondary and tertiary symptoms upon the primary may extend may be very long—may even extend to several years; but the exact term to which this interval may be extended has not been ascertained. Its duration evidently depends upon a variety of causes and circumstances (§ 115, *et seq.*).

82. vi. SYPHILIS IN CHILDREN.—*Syphilis Infantum*.—*Hereditary syphilis* differs so far from the disease as it occurs in adults, as to induce some writers to doubt its venereal origin. It is certainly the transmission of the constitutional contamination or distemper to the fœtus, during utero-gestation, and not the infection of the fœtus during parturition. The malady may exist at birth, or may not appear for some days or even weeks after birth. It is indicated by copper-coloured spots on the cutaneous surface, especially about the arms, genitals, and mouth, which may go on to ulceration. There are also a peculiar shrill or hoarse voice, excoriations and ulcerations, or an aphthous appearance at the corners of the mouth, on the tongue, throat, and palate. In more advanced stages, emaciation and a senile appearance of the countenance; snuffling, or obstruction of the nose, enlargement of the glands, general cachexia, terminating in death, if the disease be not early detected and judiciously treated, and even in such favourable circumstances the child may be carried off by some severe complication. In most of the cases of syphilis infantum the mother has been stated to have infected the fœtus. I believe, however, that the infection has not always proceeded from the mother only. SCHENCK adduces an instance (*Observ. le vj.*, No. 21) of the infection of the fœtus from the father, the mother being unaffected. It must, however, be admitted that it is very difficult to prove the mother to have been untainted by the distemper, when the father has been affected. Upon the whole, it may be generally expected that the fœtus will manifest the disease when the pregnant mother is constitutionally affected; and it is not improbable that the child may be infected by a constitutionally syphilitic father, without the mother having manifested any symptoms of the constitutional or primary distemper. MAURICEAU, however, has adduced instances of the child having been free from syphilitic taint, although the mother was affected; and I know cases of the

children being free from syphilitic taint although their fathers were constitutionally affected; but these children presented more or less of the scrofulous diathesis, or died in infancy. "The child may be also affected after birth, by a nurse suffering under syphilitic ulceration of the nipple, or by its mother under the same circumstances, if the disease of her nipple has been derived from a strange child; but no instance is known of a child infecting its own mother, although it will immediately communicate the disease to a strange nurse." The infection of the nurse is manifested by ulceration of the throat, identical with that succeeding primary disease, by cutaneous eruptions, by the formations of excrescences about the pudenda, which are capable of affecting her husband, in whom the infection is likewise followed by constitutional symptoms. HUNTER believed that secondary symptoms could no longer infect; but this opinion is disproved by many very experienced writers, and by several instances which have come under my own observation. There can be no doubt that during the 16th and 17th centuries, the communication of the distemper, and even in more recent times, by secondary symptoms was remarkably frequent. This circumstance shows the intimate connexion, if not the identity, of syphilis with yaws, sibiens, and some other diseases, which, in this and many other characters, differ in no respects from syphilis, as will be shown in the sequel.

83. Dr. Rizzi, of Milan, has recorded the results of his extensive experience of congenital syphilis, and has confirmed the remarks of Dr. COLLES. According to Dr. Rizzi, if a woman contracts syphilitic ulcerations of the breast by sucking an infected infant, mucous tubercles frequently appear on the vulva and about the anus. The syphilis, although secondary, is transmissible by contact, so that an innocent woman may communicate the distemper to her husband. Of this fact the physician should be fully aware. Of 100 persons with chancres on the breast from impure lactation, or in the mouth or throat from contact with an infected infant, 34 had tubercles of the vulva, 19 syphilitic angina, 2 iritis, 14 tubercles of the vulva and angina simultaneously, 5 tubercles of the vulva and others disseminated over different parts of the body, 6 tubercles of the vulva, angina, tubercles of the skin, and iritis, and 19 no secondary symptoms. In nurses, as well as in men infected by them, Dr. Rizzi found tubercles the most common form of secondary symptoms, and angina often superadded. Discharges, vegetations, and exostoses were rare, and buboes, when they occurred, consisted only of swelling and tension of the sub-maxillary or axillary glands. (RANKING'S *Abstract*, &c., vol. v., p. 250.)

#### V. VARIETIES OR MODIFICATIONS OF SYPHILIS—SYPHILOID DISEASES.

i. SYPHILIS ÆTHIOPICA.—*Syphilis vel Lucis Æthiopica*—*Syphilis Africana*—*Yaws*—*Sibiens*—*Sivens*.—*Pian*, *Epian*, *Fr.*—*Frambesia*.

84. This distemper has existed in Africa, certainly, for ages before the epidemic outbreak of syphilis in Europe at the end of the 15th century; and, if not identical with, is at least a form or modification of, the disease which existed in the West Indian islands when they were discovered by COLUMBUS, and which was considered as intimately resembling, if not the same

as, the epidemic syphilis of the 15th and 16th centuries.

85. The African syphilis, or the *yaws*, as commonly termed, in all respects more closely resembles the earlier manifestations of syphilis in Europe than the modern occurrences of this distemper. Indeed the few cases of yaws which I saw in Africa in 1817 agreed with the early accounts of syphilis so prevalent in Europe in the 15th and 16th centuries; not only as respected the character and severity of the distemper, but also as regarded the modes of its communication and the treatment of it found most beneficial. That the yaws in Africa is identical with the yaws or *pian* of the West Indies, is also undoubted; and it is most probable that the identity existed before the discovery of America. The descriptions of the disease, as observed in Africa and in the West Indies, agree as closely as the descriptions of any specific disease furnished by different writers, whether as occurring in negroes or in mulattoes. It is very rarely observed in white persons in modern times, as it is especially dreaded, and hence avoided by them. That it is also the same disease as the *sibiens* or *sivens* formerly seen in the west of Scotland, is admitted by those who have seen both maladies. Dr. THOMSON remarks that he possesses the notes of an old physician in Jamaica, who visited a part of Scotland where the *sibiens* was prevalent; that these notes were made without any regard to theory; and that his observations confirm the identity of yaws and sibiens. (*Edin. Med. and Surg. Journ.*, vol. xv., p. 321, and vol. xviii., p. 31.)

86. This complaint is usually preceded by severe pains in the limbs, often resembling those of rheumatism, which are most severe around the joints. The pains are attended by languor and debility, and often continue for several days without any other appearance of disease. These symptoms are generally precursory, and are succeeded by more or less fever, sometimes preceded by slight rigors. In many cases, however, the fever is so slight as hardly to be noticed. Generally the patient complains of headache, loss of appetite, and pains of the back and loins, which are exacerbated towards evening. These symptoms are continued for several days, and are followed by an eruption of pustules, more or less numerous, in various parts of the body, but especially upon the face, neck, groins, pudenda, and around the anus, vulva, &c. The eruption of these pustules is not completed over the whole body at one time, nor do they appear in any regular succession on the different parts; but while one crop is falling off, another is making its appearance in other places. Every fresh eruption of pustules is preceded by a slight febrile paroxysm. The pustules are filled with an opaque whitish fluid: they are, at their first appearance, not so large as the head of a small pin; but they grow larger gradually, until they attain the size of a sixpence or even of a shilling. When the pustules burst, a thick viscid matter is discharged, which forms a foul and dense crust or scab upon the surface. The number and size of the pustules is proportioned to the degree of eruptive fever. When the febrile symptoms are slight, there are few pustules, but they are mostly of a larger size than when the complaint is more violent. From the larger pustules red fungous excrescences frequently arise of various magnitudes,

from the size of a pea to that of a large mulberry, which fruit, owing to their rough, granulated surfaces, they somewhat resemble. These fungi, though they rise considerably above the surface of the skin, have but a small degree of sensibility. They never suppurate kindly, but gradually discharge a sordid glutinous matter, forming an ugly scab round the edges of the excrescence, and covering the upper parts of it, when much elevated, with white sloughs. When these eruptions appear upon any part of the body covered with hair, the colour of the hair is gradually changed from black to white. At the commencement of the disease, when there is any doubt of the nature of the complaint, the natives open one of the pustules and drop upon it a little of the juice of the capsicum: if it be of the yaws species, little or no pain is excited.

87. The eruption is more elevated and broader, and more numerous in the face, groins, axilla, verge of the anus, and labia majora, than in any other part of the body. The crops of yaws are various. In some there is only one copious eruption, of a healthy nature, with well-defined edges; it continues on the skin for a long time, the patient enjoying his usual health. This is the most favourable form, and in the robust and well-fed is terminated in seven or nine months. More frequently small watery yaws appear, and recede in a month or so. The patients lose flesh; become cachectic, and dropsical; but in these a nourishing diet will often, in a month or two, induce a return of the eruption in a more copious and larger form; and several crops of such eruptions may successively appear. When the disease attacks the throat, the soft parts are always lost. If there be any tendency in the constitution to hereditary or visceral disease, it is generally excited into action, especially upon the disappearance of the eruption; and caries of the bones, disease of the joints, dropsy, &c., supervene. In the successive eruptions of yaws there is often one ulcer which does not heal, but becomes larger than the rest, and if neglected is apt to produce caries of the adjoining bones. Nocturnal pains, swellings of the periosteum, ulcers of the pharynx, &c., generally attend the advanced course of the distemper; and are accompanied by chronic hectic, and general cachexia. If the infection takes place in the mouth or lips, ulcerations appear in these parts, and extend to the fauces, palate—the bones of the palate and those of the nose becoming implicated.

88. *The duration of the period elapsing from exposure to contagion to the commencement of the eruptive or febrile symptoms varied in several cases, accurately observed by Dr. Thomson, from seven to ten weeks. In some cases in which he had recourse to inoculation, the eruption appeared in seven weeks. The duration of the disease after the appearance of the eruption varies from some months to several years. It depends upon the complete eruption of the pustules. When the eruption is slight, the pustules being few and small, the hectic cachexia and complications superinduced prolong the distemper, and ultimately occasion death, the eruption having long previously disappeared.*

89. ii. SIBBENS or SIVVENS.—This form of syphilis was formerly seen in the southwest of Scotland, especially in the counties of Ayr, Galloway, and Dumfries, but is now entirely extinct. The descriptions given of it by ADAMS, HALL, GIL-

CHRIST, HOPE, BARRY, and others, show that this is the same disease as the yaws, and the syphilis epidemic in the 16th century. Indeed, yaws, sibbens, and other forms of syphilis about to be noticed, are merely modifications of the same specific distemper, owing to local circumstances, manner and habits of living, &c.; these forms being in no respect different, as to their modes of communication, from the malady of the 15th century. The syphilis of the present day is that form which has become most sensibly modified in the course of ages, but which, under circumstances of neglect, unwholesome living, want of cleanliness, &c., will in most cases assume as virulent and infectious a character as was displayed by it when first disseminated throughout Europe.

90. *Sibbens* shows itself, according to the mode of infection, in modified states, especially at its commencement. Like yaws and other forms of syphilis about to be noticed, it was communicated by sexual intercourse, by mercury, by the common use of the same utensils, of the same bed-clothes, especially when blankets only were slept in, and by want of cleanliness, and by two or more sleeping in the same bed, as not unusual in former and even in recent times. In infants at the breast, and in children, the distemper appeared first in the throat and mouth, with inflammation of the velum palati and adjoining parts, followed by a whitish eschar, or a superficial red ulcer. At the same time white spots, eschars, and small elevations of a pearly or milky colour occurred on the insides of the cheeks, lips, &c., and in these situations, excrescences, or small fleshy growths, resembling a raspberry, which became covered with a scab, were afterward developed. These excrescences were diagnostic of the malady. This state, when neglected, or occurring in cachectic or debilitated subjects, was followed by destructive ulceration and extension of the mischief to the pharynx, larynx, &c., with loss of the velum palati and affection of the bones of the nose, face, &c.

91. In others, after pains in the joints, bones, and febrile symptoms of varied duration, the disease appeared in the skin, under somewhat different aspects. The whole surface of the body was often spotted with a coppery or dusky-red eruption. In many clusters of pustules broke out, followed by successive desquamations, or scabby eruptions of the scalp, forehead, insides of the thighs, accompanied by little hard tubercles in the skin. In some tumours resembling furuncles were seen in various parts, and gave rise to ulcers which perforated the integuments. These ulcers were supposed to be produced by the virulent matter of the disease having come in contact with the surface, as when the disease had been caught by sleeping with the infected, or in the same foul blankets as had been used by an infected person. Ultimately soft, spongy, raspberry-like tumours (hence the name *frambæsia*, sibbens, sivvens) broke forth in various parts of the body. Affections of the bones were not observed by some; but BELL and others mention *nodes* and *caries*. The affections of the genitals, when not occurring primarily, owing to the contagion affecting the surface of the body, sometimes appeared consecutively. Different cases presented somewhat different appearances, manifestly owing to the parts primarily infected and affected, and to the progress the distemper had made when arrested by treatment. The disease

was often fatal in children and infants in whom it had made progress before submitted to treatment.

92. iii. *PIAN* or *EPHAN* is the term usually applied to yaws, as observed and described by physicians who have practised in the French West India Islands, and although manifestly the same disease as yaws, and as syphilis at its earliest appearance in Europe, presents a few differences in the character of the eruption, especially, according to the descriptions of these physicians. The patient experiences slight fever, with pains in the limbs and bones, and small red spots on different parts of the body. He loses flesh, and the skin becomes scaly. The intensity of these symptoms slowly decreases, but the eruption is developed, and assumes *three* aspects. The first, or *large pians*, sometimes become as large as the hand, from which fungous excrescences shoot, and a thick sanious matter exudes. The *small pians* are much less in size and more numerous than the former; their excrescences are redder and less fungous. The *red pians* are larger than the latter, but less than the former, of a flesh colour, and are developed slowly and successively; but are accompanied and followed by more serious symptoms than those of the other two varieties, particularly those of the first, which is the mildest.

93. One of the ulcers of pian generally becomes larger than the others, forming a deep ulcer of a bad character, without fungi, discharging much sanious matter. It is aggravated by the usual dressings, and is called the *mother pian*, as a similar large ulcer in yaws is called the *mother yaw*. It is dangerous to dry it up before the general infection is fully manifested. In this variety, as in yaws, if a patient has an ulcer on any part of his body before the infection of pians, the first pustules are developed upon it, and the ulcer often becomes the mother pian. This variety of syphilis, if allowed to proceed, is followed by farther alterations. These consist chiefly, 1st. Of excrescences on the soles of the feet and palms of the hand, which are tender at first, or before they break, but which, when they break, discharge a purulent matter; 2d. Of thickenings of the skin of the soles of the feet and palms of the hand. These are red, painful, tender, and hardened, but without exudation; 3d. Of wandering pains in the bones, of the tumefaction of the spongy bones and of the extremities of the long bones, attended by caries, softening, exostosis, &c. This state of the disease, called *bone-evil*, is often attended by the formation of numerous ulcers, by affection of the bones of the face, of the palate, &c.; the patient often being reduced to a horrible state. The chief difference between yaws, pian, and syphilis, in its aggravated state of secondary disease, is in the fungiform aspect of the ulcers in yaws and pian; but this state of the eruption in these affections (*Frambæsia*) is probably to be imputed to the peculiarity of the skin and habit of body of the negro, in whom this distemper was observed by those who have described it. The following accounts of the occurrence of syphilis as local epidemics are interesting, inasmuch as they exactly agree with the descriptions given of syphilis in the 15th and 16th centuries.

94. iv. *DISEASE OF ST. PAUL'S BAY (Canada)*, *Le Mal de Chicot*—prevailed between the years 1776 and 1780, not only in this locality, but also in some other parts of Canada. It was described

by Dr. BOWMAN, who was ordered by the governor to investigate the distemper. In children most frequently the disease commenced with aphthous pustules on the lips, tongue, and inside of the mouth. These advanced rapidly, and the tongue, palate, &c., were sometimes nearly destroyed by them. The whitish puriform matter exuded from them communicated the disease to others. Older patients complained of pains of the bones, and of slight febrile exacerbations, until eruptions, followed by ulcers, appeared on the skin, and in the mouth and throat, when the pains abated. These ulcers, according to their situation, which depended upon the contact of the virus, were followed, in many instances, by cervical, axillary, or inguinal buboes. At a more advanced stage the body became covered with pruriginous tetters, which soon disappeared. The bones of the nose, palate, cranium, pelvis, and extremities were ultimately attacked by nodes and caries. The frame appeared altogether contaminated, all the functions disordered; and many sunk in a state of extreme wretchedness, especially children, the weak, and neglected. Robust persons withstood the successive complications of the distemper for many years.

95. The inhabitants of the parts where the disease appeared stated that it was introduced and extended by sexual intercourse, by contact, and by foul clothing. It spared no one exposed to infection, but was most virulent in children. SWEDIAUR, admitting the imperfections of the description given of the distemper by Dr. BOWMAN, considered that it agreed with the earliest accounts of syphilis in the 15th and 16th centuries. It is also manifestly the same malady as that which was epidemic in 1800, and in following years until 1809, in districts of *Scherlievo*, *Gronemico*, *Fiume*, &c.

96. v. *THE SYPHILIS OF SCHERLIEVO*, or the epidemic which received this name from its prevalence in this locality. MM. PERCY and LAURENT state that, in this district and those adjoining it, the commission appointed to inquire into the nature of the distemper found more than 13,000 persons infected by it, out of a population of 38,000. It reappeared, or became epidemic again, in 1808 and 1809, where it seemed to have been perpetuated by the filth of the lower orders, whose damp cabins were shared with their domestic animals. The disease usually commenced with lassitude of the limbs and pains in the bones, which increased during the night. The voice became hoarse, deglutition difficult, and the velum palati, uvula, the tongue, and pharynx, red and aphthous. Soon after the aphthæ burst and discharged an ichorous matter, which eroded the adjoining parts. Ulcers afterward were formed, which extended into each other, creating sores of various dimensions, but always rounded, of an ashy colour, and with hard or raised and dark red edges. These ulcers were seated chiefly in the tonsils, uvula, velum palati, tongue, and cheeks, and were followed by caries of the bones of the face and nose, and the discharge of foul, fetid pus. The voice was more and more changed, and at last lost, from ulceration extending to the larynx. The exostoses and nodes in rare cases vanished along with the pains, as soon as a pustular eruption was evolved on the skin.

97. In many cases, after the pains in the bones a pustular eruption appeared on the surface, which M. BOUÉ states to have been announced

by itching, which disappeared when the eruption was fully out. The pustules were of a coppery colour, round, and of various extent; and appeared most frequently on the forehead and hairy scalp, on the inner surface of the thighs and extremities, and around the anus and genitals. In some cases an acrid ichor exuded from them, which excoriated the skin; in others the discharge dried and formed scabs. The disease often remained stationary in this state for a long time. After the scabs had fallen off the skin retained marks of a coppery hue, which were removed with difficulty.\*

98. The disease appeared in some cases with various-sized blotches of a coppery colour, in the centres of which ulcers were formed, from which a matter was exuded which fomed scabs similar to those which covered the pustules. These blotches were surrounded by a coppery areola. It was remarked that the female genitals were more frequently affected than the male. Dr. CAMBIERI, among an immense number of cases, found only one of gonorrhœa, which complicated the distemper. The ulcers which often eroded the scrotum were consequent upon the general infection. Buboës in the groins, or enlargements of other lymphatic glands, were seldom seen. The modes of communicating the malady were the same as those which will appear in the sequel (§ 109, *et seq.*).

99. VI. DIAGNOSIS OF SYPHILIS.—This is often very difficult; for although the distemper has generally presented a modified and milder character in modern times, nevertheless cases sometimes occur which, owing to neglect, to constitution and habit of body, to treatment and manner of living, are as virulent as many of those which were described by writers in the 16th century, or of those which have been termed *sypphiloid diseases*. It will have been remarked, from what I have stated above, that I consider these latter as identical with the early manifestations of syphilis in Europe; the differences actually observed being only such as arise from the manner of infection—from the exudation from the cutaneous and other parts, during the constitutional disease, having infected these parts in persons with whom these exudations had come in contact, and from differences of race and other circumstances (§ 109, *et seq.*). That the disease assumes a different character as respects the different races, may be expected in as far as the integuments are concerned; for, owing to the structure and vital condition and functions of the skin, and to the asthenic diathesis of the dark-skinned races, and more particularly of the negro, syphilis attacks these structures with greater severity than in the white race—although even in this there are often exceptions—and assumes in the former the characters described under the head Yaws and other Syphiloid Distempers. As regards the treatment, that found most beneficial in the one is also most beneficial in all the others. I have seen small-pox in the negro in Africa, and yaws in the same race; and the difference of the for-

mer malady in the negro from that observed in the white race is as great as that of the latter disease is from secondary syphilis in the white. The causes, efficient and concurring, are the same in character; the treatment is also the same; and this being admitted as respects yaws, the inference must necessarily extend to the other modifications of the distemper belonging to this category.

100. *The diagnosis of constitutional syphilis*, as it occurs in the present day in the white race, and after the virus has passed through many generations, is often very difficult, even when aided by the history of the case; and this difficulty is increased by the different tissues and parts which are secondarily affected, either singly or conjointly. Mr. HOLMES COOTE has classed the *secondary effects of syphilis* as follows, and to these I may add the *tertiary*:

101. i. SECONDARY SYMPTOMS OR EFFECTS.—1. *Cutaneous eruption*.—*a.* Erythema; *b.* Scaly eruption; *c.* Papular eruption; *d.* Pustular eruptions; *e.* Tubercular eruptions. 2. *Mucous tubercles, or condylomata*. 3. *Ulcerations between the toes, Rhagades digitaria*. 4. *Superficial ulcerations of*.—*a.* The meatus auditorius externus; *b.* The navel; *c.* The nose; *d.* The lips and the angles of the mouth. 5. *Syphilitic affections of the tongue*.—*a.* Excoriations of its surface; *b.* Ulcerations, fissures, &c.; *c.* Induration of its substance. 6. *Ulceration of the gums*. 7. *Ulceration of the tonsils*.—Soft and hard palate. Excoriations of these parts without ulceration. 8. *Ulceration of the pharynx*. 9. *Ulceration extending to the rima glottidis*. 10. *Affections of the eye and appendages*.—*a.* Ulceration of the eyelids; *b.* Iritis; *c.* Scleritis. 11. *Ulceration of the roots of the nails*. 12. *Alopecia, or baldness*. 13. *Ulceration of the rectum and large intestines*. Syphilitic dysentery.

102. ii. TERTIARY EFFECTS.—1. *Tubercles or gummata*.—*a.* Of the skin and cellular tissue; *b.* Of those parts passing into phagedænic ulceration; *c.* Of muscular and fibrous structures. 2. *Inflammation of the periosteum*. 3. *Inflammation and enlargement of joints*. 4. *Diseases of the testes*.—*a.* Inflammation and enlargement of one or both testicles; *b.* Atrophy or other structural lesion of the testes. 5. *Inflammation of bone and its effects*.—*a.* Pains in the bones; *b.* Exostoses; *c.* Caries. 6. *Inflammation and structural change of the eyes, eyelids, or lachrymal apparatus*. 7. *Phagedænic ulceration of the scalp*.—*a.* Without disease of the pericranium and subjacent bones; *b.* With disease of these parts. 8. *Phagedænic ulceration of the pharynx*.—*a.* Extending to the larynx, cartilages, trachea, &c.; *b.* extending upward to the bones of the nose, face, and palate; *c.* extending to and causing caries of the cervical vertebræ. 9. *General syphilitic cachexia*.—*a.* Without any prominent visceral disease; *b.* With prominent disease of the viscera, as the lungs, &c.; *c.* With paralysis; *d.* With dropsy, &c.

103. It is not to be expected that the lesions belonging to the *first* or the *second* of these classes of constitutional disease will appear singly. On the contrary, they are generally associated in various forms or groups; affections of the skin being often complicated with those of the throat, tongue, gums, &c. Affections of the joints may be conjoined with inflammation of the periosteum and bones, and with phagedænic ulcerations.

\* J. BONTIUS (*Medicina Indorum*, 4to, Lond. Bat., 1718) describes the "*Amboyna Pox*" in terms which are equally applicable to *yaws*, *sibbens*, and other varieties of syphilis, and states that the disease is indigenous to Amboyna, the Moluccas, and other Eastern islands. He says that it is identical with constitutional syphilis, but differs from it in being most frequently communicated otherwise than by sexual intercourse. He states that the remedies employed for its cure are preparations of mercury, of antimony, sarsaparilla, guaiacum, China root, &c.

Even various tertiary lesions may be accompanied with one or more of those which are secondary ; or, more correctly, certain secondary affections, such as those of the skin and throat, may persist, although one or more tertiary alterations are fully developed. Thus, in a case which I saw with Sir B. C. BRODIE, there were ulcerations of the throat, pharynx, larynx, nodes, pains in the bones, &c., consequent upon syphilitic eruptions and cutaneous ulcerations, which still remained, the pharyngeal ulcerations implicating the cervical vertebræ. The disease in this case was preceded by suppurating buboes. In another case, which I attended with the late Mr. COPLAND HUTCHINSON, there were extensive ulcerations of the skin ; nodes, caries of the bones of the nose and palate, inflammation of both eyes and eyelids, remarkable enlargement of the knee and elbow-joints, phagedænic ulceration of the scalp, and general cachexia. In other cases, in addition to affections of the bones and joints, there were phagedænic ulcerations of the pharynx, with inflammation and necrosis of the palate and nose, enlargement of the bodies of the testicles, and large ulcerating tubercles of the integuments.

104. *The diagnosis of syphilis* depends chiefly upon the history of the case, especially as respects the existence of primary symptoms, of buboes, and exposure to infection by direct or indirect contact, more especially by sexual intercourse, suckling, &c. (See the CAUSES, § 109, *et seq.*). The eruptions in the secondary stage will generally indicate the nature of the malady ; but even all that has been stated above (§ 57, 81) on this subject may not be sufficient for this purpose, if other particulars be not sufficiently considered. The colour of syphilitic eruptions, although generally yellowish or coppery, especially before they ulcerate, may be of a brighter hue if febrile action be present. In rare cases the pustular eruptions may very closely resemble the eruption of small-pox ; but a few days will disclose the differences. These eruptions and their rapid enlargement and ulceration in the early history of the distemper were very common, and hence the name of *great-pox*, very commonly given to them. Mr. H. COOTE very correctly remarks that syphilitic eruptions do not always preserve the same type in the same individual. The scaly and tubercular, or the scaly, papular, and pustular, may be combined in the same case ; and a scaly eruption may exist on the trunk and a pustular on the scalp. A scaly eruption often becomes tubercular as the constitutional cachexia advances. Scaly and papular eruptions are often coexistent, both terminating in desquamation, leaving copper-coloured stains. Large tubercles of the integument pass into deep, excavated, or phagedænic ulcers, and may be attended by the usual forms of rupia. Syphilitic scaly eruptions are generally circular, and more strictly resemble lepra than psoriasis. The eruption on the trunk is often different from that on the extremities ; on the former it is more generally erythematous, papular, scaly, and pustular ; on the latter it is often tubercular, passing into large and deep ulcers with elevated edges, especially on the lower extremities. Rupia, however, may equally affect all parts.

105. Syphilitic erythema usually precedes other eruptions, but it may continue in the form of dull red or coppery patches, or coexist with other eruptions. The most common eruption is syphilitic lepra, the scales of which are dark, and differ

widely from the silvery scales of lepra vulgaris. This eruption may extend over the whole body, causing the hair to fall off ; and affecting the palms of the hands and soles of the feet. It spreads into mucous outlets and canals, into the nasal, buccal, anal, vaginal, and others, where it causes ulcers, fissures, tubercular elevations, excoriations, discharges, &c. Lepra syphilitica often attacks and exoriates the scrotum, and is frequently attended or followed by foul ulcers between the toes, mucous tubercles about the arms, in the axillæ, groins, or where the transpiration of the surface is allowed to accumulate. The elevation of the scales of lepra into copper-coloured tubercles is always, according to Mr. H. COOTE, associated with impairment of the general health, and is an indication, during a mercurial course, that the medicine is acting injuriously, that the treatment should be changed, or at least that the patient should be allowed a more generous diet, and a moderate amount of stimuli. The cicatrices from syphilitic sores, it may be remarked, are often characteristic, being usually rounded, depressed, of a dull white hue, and irregular on the surface.

106. *The tertiary effects of syphilis* may generally be recognised with greater certainty than the secondary. The history of the case, the antecedent symptoms and lesions, however remote, and the nature of these as inferred from their characters and succession, are to be taken into account. But there are hardly any of the lesions which are termed tertiary that may not be inferred to be one of the more remote effects of constitutional syphilis, when viewed and considered with reference merely to its own characters and relations. The mere enumeration (§ 101, *et seq.*) of these effects sufficiently indicates their nature ; and are equally the results of neglected or injudiciously treated syphilis, as observed in the present day, and of the African yaws as observed by myself and others.

107. VII. THE PROGNOSIS OF SYPHILIS manifestly depends upon so many circumstances as to be stated with much difficulty, and even with uncertainty. It depends not only upon the progress the distemper has made, and upon the effects observed, but also upon the health and constitution of the patient previously to infection, and at the time of his coming under treatment. Nor should the mode of infection, and the course it has pursued, and its recurrences when the distemper has become constitutionally chronic, be overlooked. If the patient be young, in previous good health, be not exposed to fatigue, cold, or anxiety of mind, and not given to excesses of any kind, a favourable opinion may be given both in the primary and secondary stages of the distemper. But if his health, strength, and constitution be manifestly impaired ; if he be dissipated, exposed to fatigue, and irregular in his habits ; and more especially if the secondary effects be severe, be complicated, have been rapidly developed, or have reappeared after courses of mercury, or after other judiciously employed means, an unfavourable or at least a guarded diagnosis should be given, the danger of the case fully admitted, and due precautions for the guidance of the patient fully stated. In most cases ulcerations of the pharynx, owing to their disposition to extend to important adjoining parts, or to become phagedænic, should be viewed unfavourably, more especially in the circumstances just mentioned. The severer kinds of secondary effects should also be much dreaded

in infants; and they are always most difficult to remove in patients of all ages when they are produced by the now infrequent modes of infection (§ 110, *et seq.*) which commonly prevailed in the 16th century, or by the discharges or exudations of secondary sores, either directly or indirectly coming in contact with the naked cutaneous or mucous surfaces.

108. *The tertiary effects* of syphilis are always attended by more or less present or prospective danger. But the imminence of the one, or the amount of the other, will depend upon the extent of lesion already produced, upon its complications and constitutional relations and effects, upon the history of the case, and upon the effects of appropriate treatment. When pharyngeal ulceration has become phagedænic, or has extended to the larynx, to the bones of the face, and to the eyes, the patient is in great danger; and this is more extreme if the cervical vertebræ become implicated. The same prognosis may be given if, with general and increasing cachexia, pulmonary, paralytic, or dropsical disease supervene, after obstinate, prolonged, or even rapid course of the distemper; although in some of these cases life may be prolonged for a considerable time under favourable circumstances, and suitable regimen and treatment. In this far-advanced category of morbid results an opinion of the issue will be based upon experience of the effects of the most influential medicines, upon the local and constitutional associations of each case, upon the previous and existing circumstances of the patient, upon the history of the malady, and upon the various influences which have modified its course. In respect of the tertiary effects of syphilis, I may state that an opinion respecting them should always be given with caution and reservation; even although circumstances may not warrant that opinion to be unfavourable.

109. VII. THE EFFICIENT CAUSE OF SYPHILIS, AND THE CAUSES AIDING ITS OPERATION.—The former has been very generally recognised, and its effects admitted; but all the modes and circumstances of its application and operation have not been sufficiently shown and considered. The latter have been either overlooked or imperfectly estimated, especially as regards the successive changes, promoted and brought to maturity, as manifested in the secondary and tertiary results of the poison. The causation of syphilis has been studied merely from what has been observed in modern times, and from the common way of propagating the distemper at the present day. But the more general way by which this infection was produced soon after its introduction into Europe, and during its epidemic prevalence, has been altogether overlooked; although, under the circumstances existing in these ages, it may be still propagated in the same ways, and its effects present as severe a character, and the same features as those which distinguished it in former times; and which still distinguish it in that form of the distemper which prevails in Africa, and which prevailed there from immemorial ages before it was introduced into Spain.

110. The contagion of syphilis at the present day, and for many years past, has arisen from sexual intercourse, either the male or the female being the subject of the primary disease. In these cases the infection is produced by the virus, poison, or morbid secretion of the primary sore. This mode is generally admitted, and is

now, with very few exceptions, especially in Europe, the common mode, no other being acknowledged by many, the exceptions being altogether ignored. But I have had sufficient reason to conclude that whenever a secondary venereal ulceration, seated on the integuments, or in the mouth and throat, produces a secretion or discharge which comes in contact with a mucous surface, or with an abrasion of the cutaneous surface, or is even allowed to remain in contact with an unabrased surface, infection is liable to take place, and that this liability exists both in children and in adults. The communicability of secondary syphilis, especially when the sores have proceeded to secrete or produce a fluid exudation, was a well-recognised fact in former times, and has been witnessed by myself during the course of my experience in several instances. It was a recognised fact by Dr. COLLES; and although HUNTER believed that secondary symptoms could no longer infect, Mr. BABINGTON remarks, when commenting on this belief, that "the facts (that they do infect) are so well established, that it is more easy to question the principle than to doubt the facts."

111. Judging from what I have seen in several countries and climates, and in children and adults in this country, I conclude that the morbid secretion from secondary sores, if allowed to remain in contact with the more susceptible surfaces or parts of a healthy person, will infect that person, provided that he be predisposed to, or susceptible of, the infection; and that the local contamination, at first confined to, and more particularly and severely affecting, the tissues first infected, will become general, and will the more readily and severely, by means of the secretion from the ulcers or sores produced in the course of the distemper, infect those to whom this secretion is either directly or indirectly applied. This mode of communicating the malady was often observed in all the varieties of it described above as syphiloid diseases, and in the usual manifestations of the malady, from the end of the 15th until the close of the 17th century, or even later. The extensive prevalence of syphilis during these centuries, although imputed by many, and probably not without reason, first to a leprous diathesis, and afterward to a scorbutic diathesis, or to a complication of syphilis with leprous or with scorbutic symptoms, may be more correctly accounted for by the facts of the secondary, or early constitutional effects of the malady having become thus virulently contagious, both by this mode of communication, and by its successive propagation in this manner.

112. If we note the habits of the lower classes in those ages, the ready infection and the severity of syphilis are easily explained. As observed in the present day, with respect to yaws in negroes, the contagion was produced by the secretion from the sores on the cutaneous surface, by mediate or immediate contact, much more frequently than by sexual intercourse. In the lower classes in Europe, in the 15th, 16th, and 17th centuries, the circumstances favouring this mode of communicating the malady were much more remarkable than in the negro, with whom the disease most probably originated; for among this race its antiquity appears to have been the greatest, and by this race the distemper was communicated to the Moors and Jews in the north of Africa, and by them conveyed into the south of

Spain, where it existed long before the expulsion of them from the Iberian peninsula.\* The lower classes in Europe during the centuries of the earlier prevalence of syphilis were remarkable for their neglect of cleanliness, for their use of woolen night and day clothes next to the skin; for the habit of two, three, or more sleeping in the same bed, often in a state of nudity; for drinking and eating out of the same vessels; and for these and other social conditions favouring the communication of the disease, in its secondary stage, independently of sexual intercourse.

113. With the progress of civilization, and with the knowledge acquired of the communication of the distemper by these means, the infection of it otherwise than by sexual intercourse became less frequent, and the virus more generally having to pass through the absorbent system, when the genitals were the seats of primary infection, was either arrested in the course of its constitutional contamination, or rendered more mild, and slower in producing its successive specific effects, than when infection was produced by the virulent secretions from secondary sores applied to parts which more readily admitted of constitutional contamination. The successive propagation of the distemper in this latter mode, and generally without the intermediate interruption and amelioration resulting from the action of the virus on absorbent glands, without the production of buboes, manifestly rendered the malady more rapid and more severe, and was the chief cause of the early prevalence of syphilis being in some respects different from what is observed of it at the present day, but in every respect similar to the varieties mentioned above (§ 84, *et seq.*); many of the influences producing these varieties actually having existed at the time of, and for ages after, the introduction of syphilis into Europe.

114. As observation rendered persons aware of the habits and circumstances causing and favouring infection, more especially in the higher classes of society, these habits were reformed or refrained from. Persons no longer drank out of the same glass or cup, or slept in a strange bed, without due precaution; and much of the manners of modern times originated either in precautions against infection, or in evincing a confidence that no precaution was required. But in whatever manner the infection may be produced, whether by primary sores on the genitals, where the morbid secretion was favourably placed to operate its effects, or by the secretions from secondary sores or ulcers in the cutaneous or in the mucous surface, under circumstances favouring their operation and consequent contamination—now occurring very rarely, in former ages very frequently—there are a variety of causes or influences which aid the efficient or exciting cause

—the syphilitic poison—in developing, hastening, or in aggravating its constitutional or contaminating effects. These are so diversified and yet so influential, whether acting simply or in combination, as to require a brief but particular notice; and are first *predisposing*, and next *concurring* and *determining*.\*

115. A. The chief *predisposing* causes of syphilitic infection are infancy, childhood, and early age; delicacy of constitution, original or acquired; debility or temporary exhaustion; debauchery, fatigue, and irregularities of any kind; and the neglect of all those habits and social observances which constitute modern civilization. The precautions observed in several cities and places against the propagation of the distemper manifestly tend not only to render it less frequent, but also more mild, than in other countries where no precautions are instituted, especially among those who more commonly are infected by, and who communicate the malady. But the predisposition, however produced, or in whatever form it may exist, favours not only the primary infection and effects, but also the development of the secondary or constitutional disease, and the tertiary results, if the morbid procession be not arrested by treatment; and, according to the amount of predisposition, will be the rapidity with which the morbid effects are produced. Doubtless cases are not unfrequent which evince no particular predisposing cause of the infection, or of the rapidity or severity of the results; but these may be imputed to a diathesis, or some unascertained cause favouring the operation of the poison, or to susceptibility of infection and contamination inherent in some constitutions.

[\* M. VIDAL has clearly proved that secondary accidents are transmissible, and the same doctrine is supported by the following British and American authorities: SIR ASTLEY COOPER, *Lectures on Surgery*, by TERRELL, Am. ed., p. 497; MR. LISTON, *Elements of Surgery*, by DR. GROSS, p. 205; MR. COLLES, *On Venereal*, p. 263; MR. WALLACE, *On Venereal*, p. 335; MR. HENRY, *Med. Chir. Trans.*, vol. vii., 1830, p. 541; JESSE FOOT, *On Venereal*, p. 402; H. MAYO, *On Syphilis*, p. 122, 123; SIR B. BRODIE, *Le titre in London Lancet*, Feb., 1844, p. 677; MR. BARINGTON, *Notes to Hunter*, Am. ed., p. 321; MR. LAWRENCE, *Lectures on Surgery*, London Med. Gazette, March, 1830, p. 806, 807; MR. PORTER, *Lectures on Syphilis*, Dublin Med. Press, Feb. 17th, 1847, p. 99; MR. WHITEHEAD, *Illustrations of transmitted Syphilis*; SAMUEL A. LANE, *Lectures on Syphilis*, London Lancet, May 28th, 1842, p. 294; MR. BACOT, *On Syphilis*, p. 252; MR. CARMICHAEL, C. in *Lectures on Venereal Diseases*, p. 51; LANGSTON PARKER, *Modern Treatment of Syphilitic Diseases*, 2d ed., p. 163; MR. EGAN, *On Syphilitic Diseases*, p. 233, 234; I. SMITH WILSON, *On Syphilis*, p. 36; GEORGE M'LELLAN, *Princ. and Prac. of Surgery*, p. 250, 251; DR. NELLIGAN, *Dub. Quar. Journal of Medicine*, Feb., 1853, p. 119; DR. CAMPBELL, *North. Journal of Med.*, 1844; or *Cornwall's Journal*, Sept., 1844, p. 773; JOHN L. CORMACK, *London and Ed. Monthly Journal of Medical Science*, Sept., 1844, p. 773; EVANSON and MAUNSELL, *On Diseases of Children*, Am. ed., p. 350; JAS. STEWART, *On Diseases of Children*, 4th ed., p. 468; DR. WATSON, *United States Med. and Surg. Journal*, vol. ii., p. 103; DR. H. D. BULKLEY, *On Syphilis in Infants*, New York Journal of Medicine and Surgery, Oct., 1849; GEO. C. BLACKMAN, Amer. ed. of VIDAL *On Venereal Diseases*, p. 55. This question is very ably and successfully argued by VIDAL in opposition to RICORD, who very inconsistently admits the infection of the nurse by the child and the contagiousness of the mucous tubercle in the adult—in other words, physiological inoculation, while he denies the fact of experimental inoculation. M. MALGAIGNE has very happily, in few words, characterized this author as follows:

"M. RICORD, possessed of a theatre of observation vast as could be wished, began by rejecting the observations of others; then, adopting a certain theory, he disregards those of his pupils made under his own eye, in his own service; and finally, I must say it, he takes no heed of his own when they conflict with his own preconceived views."—*L'Union Medicale*, Aug. 30, 1851.]

\* DR. WINTERBOTTOM (*An Account of the Native Africans*, see vol. ii., p. 148) remarks that "the yaws is not mentioned by authors as a disease which occurs in Egypt, though, from the frequent communication of that country with those parts of Africa in which the disease is endemic, we might be led to expect that it would be imported. There is reason, however, to suppose that the yaws does actually appear there, though mistaken for the venereal disease." He proceeds to remark that a "Capt. who professed to cure the venereal disease in its advanced states, prescribed 'two coffee-cups of flax oil to be taken every morning fasting,' directing no regimen farther than to keep the patient warm. The pustules and other eruptions he covered with a red earth common in some parts of Egypt. They gradually became dry, and left no mark. At the end of three months a cure was effected. It is farther stated that those persons who have been affected and fully cured have no fear of a second infection."

116. That all persons who have not been previously constitutionally infected are liable to syphilis, provided that the virus is applied in sufficient quantity, or is allowed to remain in contact with a part upon which it is capable of acting, may be inferred; but there is reason to conclude, from what has been observed in persons previously infected, that a second constitutional infection of syphilis rarely or never takes place, and that such an occurrence is merely the return, or the re-development, in a state of active manifestation, of the disease, which had been lurking in a latent state in the body, and which various influences had reproduced independently of any second local infection. While, therefore, all previously uncontaminated are liable to syphilis, those who have been thus diseased are not liable to a second constitutional infection, provided that they have been completely cured; but they are liable to a return in an aggravated form of the secondary or tertiary disease, if it have not been completely eradicated, especially if they are exposed to the causes about to be noticed (§ 117, 118); or, in other words, that constitutional syphilis, when cured, renders the body unsusceptible of a second constitutional infection.\*

117. *B.* Several causes favour, 1st, the development of the constitutional disease from the local infection or primary sores; and, 2d, the aggravation and local manifestations of the syphilitic contamination, when it is not completely removed, but remains lurking in a more or less latent form, in the body. The most remarkable features of constitutional syphilis are the severe and even dangerous developments sometimes assumed by it after it has remained for several, or even for many, years latent in the frame. These cases present two difficulties—first, to estimate the influence of the poison in affecting the vital cohesion and conditions of the tissues in so permanent a manner as to render them liable to ulterior changes and disorganization after very remote periods;

\* We are by no means convinced that syphilis can only occur once in the same individual. No fact is better established than that a person may have repeated attacks of the disease, especially of the milder forms. Syphilis, like other diseases, occurs under various forms and in various degrees of severity. The virus may only induce a chancre, which is readily cured, leaving the constitution perfectly sound; or it may produce caries, necrosis, various visceral affections, and profound cachexia, from which it is very doubtful whether a patient ever entirely recovers. If, under the latter circumstances, a person exposed to new infection has a new bubo or chancre, the advocates of the *unicity* of syphilis maintain that it is only a relapse, and not the result of the recent inoculation. Statistics are wanting on this subject, but it is stated by M. VIDAL that M. BOULEY, physician of the Louvre in Paris, produced a second syphilitic infection in a woman labouring under genuine tertiary symptoms by inoculation. The obstacles in the way of settling this question conclusively are, the difficulty of finding cases so complete that we may know that the syphilitic diathesis is exhausted, that it has produced all it can produce; and, 2dly, to collect under one head a sufficient number of cases to form statistics, the result of which may be considered a pathological law of real value. When we consider the varying durations of syphilis, its modifications in different constitutions, the suppression of many of its manifestations by treatment, its relapses from various causes, &c., we shall perceive at once the difficulty, if not impossibility, of establishing any such law. In cases of typhoid fever, variola, rubella, pertussis, &c., no great difficulty exists, inasmuch as they are acute diseases, continuing but for a short period, and most persons are liable to repeated exposures. At any rate, this question cannot be settled till it is ascertained what is the duration of the *primary*, *secondary*, and *tertiary* stages of syphilis, how long it takes to expend its full force, and, indeed, whether confirmed syphilis is ever perfectly curable, which is denied by some of the ablest syphilographers. See VIDAL, *Ann. ed.*, p. 230.]

and, *second*, to recognise the effects of constitutional remedies upon these vital conditions and consecutive changes, and to determine how much of these effects may be imputed to the operation of the means employed, and to the efforts of nature, or of the vital resistance opposed to successive changes. It is impossible for these difficulties to be overcome without a satisfactory knowledge of the various circumstances which thus tend to develop the constitutional infection, and to aggravate this infection into dangerous local disease.

118. Observation satisfactorily and extensively conducted will demonstrate that all depressing influences acting upon the body after infection has been produced will favour the supervention of the secondary upon the primary disease; and will even more remarkably develop the latent constitutional taint or contamination, wherever it exists, into active disease and disorganization. Among these aiding and determining causes may be mentioned anxiety of mind, and fears of the consequences of infection; fatigue, debauchery, drunkenness, venereal excesses, unwholesome and insufficient food; want of sleep and sufficient repose; excessive exertion, exposure to extreme ranges of temperature; moist states of the atmosphere; and exposure to malaria in any form, more especially miasmatic exhalations in hot countries. While these causes aid the constitutional infection in accelerating the changes resulting in local disorganization, they also counteract the vital resistance opposed to these results, and throw down the barrier which the vital force raises for the protection of the organization.

119. *C. Infection of the Fetus by one or both Parents.*—*Congenital syphilis*, or the direct transmission of syphilis to the unborn fœtus, is a subject of considerable interest. That the syphilitic taint is more frequently in the father than in the mother appears manifest; but it is not so evident that the disease is conveyed directly from the father by means of the seminal fluid to the ovum, for the father may first infect the mother, the disease being afterward communicated by her to the fœtus. Secondary syphilis, however, being a constitutional taint, like other constitutional taints, it may be transmitted to the offspring from either parent, in a more or less modified form. There can be no doubt, also, that secondary syphilis may be communicated to married women by their husbands without pregnancy having taken place; or even to them or to any one else by close contact, independently of sexual intercourse, when the circumstances stated above (§ 112) favour the infection.

120. Dr. PORTER mentions the case of a lady who had become pregnant three months before the father's first contraction of syphilis, and whose fœtus died within a week from birth of unmistakable lues. The circulation of the mother had therefore been poisoned at a considerable time subsequently to impregnation, although the father had never a sore capable of furnishing a drop of matter, and the mother never a symptom of any description, until an eruption appeared a few days before her delivery. Dr. PORTER believes "that the semen of a diseased man deposited in the vagina of a healthy woman, by being absorbed, may contaminate that woman without the necessary occurrence of a chancre or any open sore secreting matter in either the man or the woman." Mr. HOLMES COOTE very correctly remarks (and his

remarks bear out my own observations in a variety of cases) that "when the mother has once been infected with the syphilitic poison it becomes extremely difficult, if not impossible, to say when the taint will become extinct. The immediate effect, as regards the fœtus, is to cause its death *in utero*. As the poison becomes less virulent, the child is born with the disease, and perishes in a few days or weeks. Then comes a class of cases in which the characteristic eruptions break out some weeks or even months after birth; but the exact limits of these periods have not been, and perhaps cannot be, accurately ascertained. In illustration of these remarks, I refer to the two following cases. In the first a respectable woman is infected by her husband. She is delivered consecutively of three dead children. At the expiration of thirteen years she gives birth to a living child, which is covered by the usual eruptions shortly afterward. In the second, a fine healthy-looking young woman is infected by her husband a few weeks after marriage. She is delivered of a dead child; after which she does not again become pregnant. But, eight years having passed, she suffers in her own person from the original taint." (*Op. cit.*, p. 129.)

121. While I was physician to the Infirmary for Children, cases illustrative of the above remarks, as well as of the following statements, were occasionally brought under my observation. 1st. That an infected mother may not communicate the disease to her infant. 2d. That an infected mother is very liable to transmit the distemper to the fœtus or infant. 3d. That the mother has been infected several, or even for many years, has given birth to one or more dead children, and has had at last a living child, which soon after birth presented the syphilitic cachexia, with anæmia, copper-coloured lepra, and ulcerations of the nose, mouth, anus, or genitals. 4th. The mother has had syphilis communicated to her by her husband; and the disease has disappeared, but she has been delivered of dead children; and after a number of years from the infection by her husband, the distemper has appeared in the throat and bones of the palate, or in other parts. 5th. The mother has been the subject of syphilitic eruptions, &c., has been apparently cured; but after many years has had a return of secondary symptoms, and been pregnant, either in the interval or at a later period. The child when born, has been, and has continued in good health for several months or years, but has presented secondary symptoms subsequently. 6th. A woman has been the subject of secondary syphilis—of syphilitic eruptions, &c., and has communicated the distemper to the child given to her to nurse. 7th. Secondary syphilis in a child has been communicated to another child with which it has slept, the severer forms of secondary disease resulting. 8th. Secondary syphilis in a child has been by it communicated to its nurse, who has soon afterward experienced the characteristic syphilitic eruptions, sore throat, alopecia, and other still more severe affections. 9th. A healthy woman has suckled, even for a few times, a syphilitic infant, and the secondary disease has been communicated to this woman by this infant; she afterward has suckled her own infant and given it the distemper.

122. These statements have been fully confirmed by my experience at the institution mentioned above, and in private as well as in gratu-

itous practice, during a number of years, and will readily be admitted by other experienced physicians. Indeed, they are fully confirmed by the writings of Dr. COLLES, Mr. H. COOTE, and by nearly all the old writers on syphilis. Dr. COLLES remarks that the child may be infected after birth by a nurse suffering syphilitic ulceration of the nipple, or by its mother under the same circumstances, if the disease of her nipple has been derived from a strange child; but that no instance is known of a child infecting its own mother, although it will immediately communicate the malady to a strange nurse. The infection of the nurse by a diseased infant manifests itself by syphilitic affections which cannot be distinguished from that succeeding primary disease—by ulcerations of the throat, &c., by cutaneous eruptions, and by the formation of moist excrescences about the pudenda, which are capable of infecting her husband, in whom they are likewise followed by constitutional effects. In him the ulceration of the throat has not the same venereal character; it is superficial, and its surface is covered with patches of whitish lymph. Dr. COLLES believes that the disease may be further imparted to other members of the family by contact, the use of the same utensils, &c., for it is remarkable, he adds, that its contagious property increases as it extends farther from its source. Its symptoms, he states, bear an exact resemblance to each other in different individuals; and in this third remove from the source of contagion, it is permanently fixed in the parts it first seizes, and is of a much milder nature. If we compare the histories of the manifestations of syphilis in different ages, as furnished us by the most trustworthy writers down to OESTERLEN, WALLACE, and to still more recent authors, we are compelled to conclude that syphilis is one specific malady, that it presents various modifications resulting from modes of infection, race, treatment, and other influences; all its varieties being traceable to one stock or source.

123. *D. INFERENCES.*—As the result of observation and research, I conclude, 1st. That syphilis, in the various forms and modifications it has presented in different ages and localities, is derived from, and hence originally identical with, the indigenous yaws of the native Africans. 2d. That this identity or derivation is proved by the characters of both forms of disease, by modes of infection or contamination, by the susceptibility and unsusceptibility of both, as shown by inoculation,\* and by the same treatment being appropriate to both. 3d. That the indigenous African or Ethiopic syphilis was communicated to the Moors and Jews in the north of Africa, and thence conveyed into Spain, and probably also into France and the north of Italy, even before the discovery of America. 4th. That the distemper was farther diffused and rendered epidemic or pestilential by the expulsion of the Moors and Jews from Spain by Ferdinand, towards the end of the 15th century, and by the distresses consequent upon this act; the miseries and the horrible sufferings resulting from it, as well as the diseases diffused by it, being recorded by contemporary writers. 5th. That this occurrence shortly preceding the

\* The yaws are inoculated at an early age in many places in Africa, in order to prevent subsequent infection; and syphilization is now practised in some places in Europe to prevent infection, as well as to produce a permanent cure of constitutional syphilis (see syphilization in the sequel).

invasion of Italy by Charles VIII. of France, by augmenting the sufferings and distresses of the inhabitants, increased the spread of the malady, and rendered it at the same time more virulent, acute, and fatal. 6th. That the diffusion, severity, and the infectious character of the malady were promoted by the distresses then prevalent in those countries, and for many years afterward, by the prevalence of a leprosy, or of a scorbutic diathesis in many, and by the habits and social conditions of communities in those ages and countries. 7th. That there is sufficient evidence to conclude that the disease existed as now stated, and had been propagated extensively, before the connoted malady, the *yaws*, or *pian*, or *epian*, which was said to have existed in America when discovered by COLUMBUS, could have been conveyed by his followers into Europe. 8th. That the manifestations of the distemper, usually described as varieties of it—as *yaws*, *epian*, or as syphiloid diseases, or as pseudo-syphilis;\* the chief of which are noticed above (§ 84, *et seq.*), are merely modifications of the malady resulting from modes or sources of infection, race, social conditions and habits, food and regimen, neglect of cleanliness, treatment, &c., as already insisted upon (§ 111, *et seq.*). 9th. That whatever lowers the vital forces of the economy, and more especially a combination of causes producing this effect, will favour the infection of syphilis, the development of the constitutional contamination, and the outbreak of the distemper when it lurks in the body. 10th. That the parent tainted by syphilis will often, but not always, communicate the disease in a more or less severe constitutional form, with marked local affections, to the fœtus—with a severity often sufficient to destroy the life of the fœtus, either previously to or soon after parturition; and that, in many cases where the venereal taint has not been congenital, serofulous diathesis or more manifest tubercular disease will result. (Sec § 82, *et seq.*) 11th. That many of the circumstances and social habits which have been shown above to have favoured the dissemination and severity of syphilis for ages, after it was introduced into Europe, now no longer exist, excepting in limited localities; but when they have existed in more modern times, the distemper has presented a severity, and other characteristics displayed by it in former ages. 12th. That there is reason to believe that the disease existed in China from time immemorial, or at least ages before the period at which it became epidemic in Europe; but the extent, or the form, of its prevalence in that country at the present day I have not the means of knowing.† 13th. That inoculation, as prac-

tised for ages on children by the negroes on the Gold Coast, for the prevention of yaws, and as lately had recourse to on the Continent against syphilis (see *Syphilization*, § 155, *et seq.*), may be expected to lead to some important results.

123.\* IX. TREATMENT.—i. HISTORY OF.—It would appear, from the earliest writings respecting the discovery of America, that the disease existing in Hispaniola, when discovered by the Spaniards, was a variety of syphilis, if not the same distemper, or the same as the yaws existing at the same time, and for centuries previously, in Africa (see § 84, *et seq.*); that this disease was treated successfully by the natives of Hispaniola by the decoction of guaiacum; and consequently that guaiacum was employed by the Spaniards who had there contracted the disease. We accordingly find many of the early writers on syphilis, especially from the commencement to the middle of the 16th century—as DE HUTTEN, DELGADO, FERRO, POLL, ZENE, GALLUS, MICHEL, RYFF, BONCOSSUS, HUSCIARDUS, &c.—recommend guaiacum for its cure. Although a very few writers mention, towards the close of this century, mercury as a remedy for syphilis, yet it was not until the middle of the 17th century (1649) that BONNJORNIER asserted that this malady could be cured by mercury alone. Some years afterward, MENDEZ (1668) and VON HAMMON (1674) proposed the question, whether or no mercury should be preferred to guaiacum in the treatment of syphilis? Since then, and especially from the commencement of the 18th century until the beginning of the 19th century, mercury has been the almost universal remedy for this distemper; and corrosive sublimate was the most employed preparation of it; more than one hundred writers (117) during the 18th century alone recommending it. CIEZA and BLANCARD prescribed sarsaparilla; the former stating that this medicine was adopted by the native Peruvians for the cure of syphilis, as it prevailed among them; and numerous Spanish and Portuguese writers in the 16th and 17th centuries employed it, in conjunction with guaiacum and sassafras; this combination being very generally resorted to as a part of the treatment of syphilitic cachexia down to the present day.

124. Early in the 18th century, WILLOUGHBY (*Salivation shown to be of no use or efficacy in the cure of the Venereal Disease*, 4to, Lond., 1723) contended against the practice of salivation, then so generally adopted; and in 1779, COCKBURN affirmed that all venereal ulcers will heal under a local treatment merely, and that mercury should be resorted to only when constitutional symptoms appear. Early in the present century several army surgeons, probably instructed by their observations in Spain and Portugal, where the practice followed before the general introduction of mercury still lingered, proclaimed the treatment of syphilis without mercury; and from 1820 to 1830, experiments were made in the hospitals of Sweden—a country where scientific progress is always in advance—and in Hamburg, on the non-mercurial treatment of this distemper. In the

\* SYDENHAM believed the yaws to be the same disease as syphilis. The writer of the article "*Epian*," in the "*Encyclopédie Méthodique*," has classed it, the yaws, and venereal disease as the same maladies. "*Epian*. Nom que les naturels de Sainte-Dominique donnoient à la vérole, qu'on croit avoir été endémique dans cette île. Quelques-uns ont cru que c'étoit un caractère de maladie plus grave et plus fâcheux encore que la vérole; mais il est actuellement prouvé, que c'est la même maladie que les François ont appelé mal de Naples, et les Italiens mal François, chacun s'effrayant de découvrir l'origine d'un mal aussi honteux, et accusant ses voisins d'en avoir propagé la contagion." (*Tome vii.*, p. 2.)

† My relative, Mr. TOTTINGER, who passed some time in China, informed me that syphilis appeared to be a disease of great antiquity in that country, and that the primary sores caught by Europeans from Chinese females generally assumed a phagedenic or sloughing character. The constitutional affection rarely occurred. He states, in answer to my inquiries, that the disease appeared indigenous to the country; that secondary symptoms are

not more frequent among Europeans in China than elsewhere; that the phagedenic form of chancre was very common, but the round indurated ulcer was often met with, and was extremely obstinate; that as the phagedenic sore progressed towards a cure, much hardness appeared about its edges; and that it was then necessary to make the gums slightly tender in order to heal it up completely.

present day there can be no doubt of the success of this treatment in the majority of cases; and that the worst states of the disease—the most prolonged and most dangerous forms—have been those for which mercury had been most abundantly employed at an early stage, and the most copious salivation produced and continued for the longest periods.

125. In the summer of 1825 the iodide of potassium was first prescribed by me for the cure of secondary and tertiary syphilis, and the prescriptions were then prepared by Mr. MORSON, the well-known operative chemist, who also, about the same time, prepared for me an iodide of sulphur, in order to employ it in similar cases; but I soon relinquished the internal use of the latter for the former, as being, even in small doses, too irritating to the digestive mucous surface. In the following year I had recourse, in the case of E. L., Esq., M.P., to the use of iodine. This case, the nature and history of which was well known to Mr. C. BEEVOR, of Upper Harley Street, had been treated unsuccessfully by mercury in every conceivable form and combination; and when it came under my care I viewed the severe symptoms, which were seated chiefly in the large joints, as the result of the combined effects of syphilis and mercury. Iodine was had recourse to successfully in this case. The correspondence between this gentleman and myself respecting the treatment during his absence from London is still preserved by me in proof of the early and successful employment of iodine and its preparations for secondary and tertiary syphilis.

126. Since 1825 I have prescribed these preparations whenever I have been consulted in cases of this nature; but in some, and in certain stages and states of the disease, they have failed, as in two instances which lately came before me, and which I remitted to the care of Mr. H. LEE, for the employment of his plan of mercurial fumigation. Most of the severe and dangerous cases of syphilis which I have had an opportunity of witnessing have been reduced to this state by an excessive or an improper use of mercury; and it has been more especially in those cases that the use of iodine, especially the iodide of potassium, has been most successful. The worst symptoms, which have been too frequently ascribed to local manifestations of syphilis, especially affections of the periosteum, bones, &c., have been demonstrated to me to have been the results of excessive doses of calomel alone, very commonly given in hot countries, during the early part of the present century, for the cure of fevers. At one period it was attempted to bring the system under the influence of mercury in these maladies, but the practice very generally failed; and in some of these cases, in which recovery took place, disease of the periosteum was the result.\*

\* The following interesting case illustrates this fact: it occurred more recently than the period above referred to. Some years ago a gentleman trading to the west coast of Africa was attacked by fever, and was treated by calomel given in scruple doses every three or four hours. He recovered from the fever, and returned to England. I was called to see him soon afterward, and found him completely hemiplegic, with two large swellings of the pericranium. Having heard the account of his case, that he had never any venereal symptom, primary or secondary, that he had taken an excessive quantity of calomel during the attack of fever, I inferred that a tumour of the dura mater, as well as of the pericranium, had resulted from the calomel, and now pressed upon the brain. The iodide of potassium was therefore prescribed, and he rapidly recovered the use of his side, the paralysis disap-

127. ii. TREATMENT OF PRIMARY SYPHILIS.—*A. The intentions of cure in this stage of syphilis are, 1st. To destroy the poisonous ulcer and heal the part as soon as possible; and, 2d. To prevent the contamination of the constitution. The first intention is best accomplished by touching the sore with nitric acid, nitrate of silver, or any other escharotic. The penis may afterward be wrapped in a rag dipped in warm water. An aperient may also be given, and rest and low diet enjoined. If the sore have lasted above a week, it may still be expedient to destroy it; but there will not be the security against constitutional contamination which an earlier recourse to these means might afford. When, however, the chancre consists of a well-marked indurated lump, or when the penis is swollen and inflamed, the patient feverish, or when there is swelling or tenderness in the groin, then the above local treatment is no longer applicable; and mild liquid applications, consisting of the black wash, lotions containing tannin or catechu, or of other substances capable of decomposing the contaminating secretions, may be prescribed to the affected parts. If there be much irritation, the penis should be enveloped in a poultice, or in a fomentation of boiled chamomile flowers and poppy heads, and the patient kept in bed. If induration exist, an ointment with calomel may be applied. "Afterward, during the indolent and granulating stages, the sores may be treated with any astringent lotion, and be touched occasionally with nitrate of silver or sulphate of copper." (DRUITT.)*

128. *B. The prevention of the constitutional contamination of syphilis was formerly attempted by a recourse to mercury contemporaneously with the treatment of the primary sores, the belief being general that where this object was not attained by means of this substance, the disease would infallibly proceed from bad to worse. Had, however, the malady been studied with a due reference to its origin and to its treatment, during the earlier periods of its history, as well as to the treatment of the connate malady, of which I have contended that it is merely an extension and modification, a different method of cure would have been instituted; and a recourse to mercury would have been either reserved or entered upon in such a manner, and with such precautions, as would have secured successful results. The modern opinion, however, is, that every case of primary syphilis may be treated without mercury; that the too profuse administration of it may render the disease infinitely worse; that there are many cases which do not admit of it at all; but that in the right cases the moderate and judicious use of mercury removes the existing symptoms, and renders the patient far less liable to a relapse.*

129. Mercury is either not required or not admissible under the following circumstances: "When the primary sore has been destroyed, or has healed within seven days from its commencement; when it is much inflamed, irritable, sloughing, or phagedænic; when the patient is feverish and irritable; when a bubo is present; when the health or constitution has suffered from attacks of syphilis or the use of mercury; when mercury

pearing with the subsidence of the pericranial tumours. He has continued in good health up to this time.

While this was passing through the press I was called to a lady similarly affected to the above case, after the prolonged use of mercury for hepatic disease. The iodide of potassium has already been very beneficial to her, but sufficient time is not yet elapsed to show the full results.

is known to cause rapid salivation, or to occasion loss of flesh, sore throat, night sweats, or mercurial erethism; and when scrofulous disease is manifestly pronounced, or when tubercular consumption is fully developed. If there be none of these contra-indications, and more especially if the sore be indurated, mercury may be given, not because absolutely necessary to a cure, but because it has been proved by experience to hasten the cure of the primary, and to lessen the chance of secondary symptoms." (DRUITT.)

130. But, as Mr. H. COOTE has justly stated, "every form of primary syphilitic disease may be followed by constitutional affections, the nature and the duration of which no one can predicate," whether the treatment be mercurial or non-mercurial. The want of fixed opinions as to the treatment of the disease, displays itself in all the countries of Europe; and although it causes much uncertainty and distrust of the use of remedies, the injurious recourse to the excessive use of mercury, so common in former times, is no longer adopted. The most important question, however, is the frequency of constitutional disease after primary syphilis, when treated with, or without mercury; for the primary affection is, in by far the greatest number of cases, an evil of comparatively little magnitude. Secondary syphilis, when once established, is a disease of which no one can foretell the termination. Its various phases, their succession and complication, are almost beyond the reach of our knowledge, and often out of the sphere of treatment. Dr. HENNEN treated 105 cases of primary sores without mercury; secondary symptoms followed in eleven instances, and all these were cured without mercury, excepting one obstinate case. In the report of the Army Medical Department, from December, 1816, to December, 1818, 1863 cases of primary chancre were cured without mercury out of 1940 cases, ninety-six having had secondary symptoms; the average time required for their cure being twenty-one days when bubo did not exist, and forty-five days when bubo was present. The average time for the cure of secondary symptoms without mercury was from twenty-eight to forty-five days. In the above period, 2827 cases of primary affection were treated with mercury; secondary symptoms occurred in fifty-one of them. The average time for the cure of primary symptoms without bubo was thirty-three days; with bubo, fifty days; and for the cure of secondary symptoms, forty-five days. Of thirty-two cases treated by Mr. GREEN without mercury, buboes occurred in sixteen cases, six only suppurated, and constitutional disease, preceded by febrile symptoms, followed in nine cases.

131. From these data it will be seen that the balance of advantages is not much in favour of mercury; and yet there are a few cases which cannot be cured, or at least not so soon or certainly cured, without this mineral, when used in a judicious manner. The opinions of some of the ablest recent writers as to the use of mercury for primary syphilis appear to accord with those of H. LEE, DRUITT, and ACTON; and upon the whole, with the results of my own experience, which agrees also with the following remarks by Mr. HOLMES COOTE: "I am far," he states, "from undervaluing mercury as a remedy in syphilis; on the contrary, it is the most certain and powerful remedy we possess; but it requires to be administered with caution. The best method of secur-

ing a patient against the invasion of secondary symptoms is by destroying the primary sore, when small and manageable, by caustic; next, by healing the primary sore when that measure is impracticable as quickly as possible without detriment to the patient's health. If we salivate a patient in whom a small superficial sore is running its usual brief course of two or three weeks, we positively do the man an injury. But if induration should occur, either in the base of the sore as in the indurated chancre, or in the cicatrix, a course of mercury, judiciously administered, is invaluable." The rules which should guide the treatment of chancres, are, 1st. To destroy, as rapidly as possible, the syphilitic virus, by applying the nitrate of silver, the strong nitric acid, or the acid nitrate of mercury, or the Vienna paste, to the sore when it is small, and spreading, but without induration; 2d. For sores which are not indurated, spread feebly, and show signs of incipient granulation, the administration of mercury is injurious, as retarding the healing process, and not protecting the patient from secondary symptoms; 3d. When induration exists in the slightest degree in or around the sore; when the chancre continues to spread quickly, or when, after seven days, it shows no disposition to heal, then mercury is required; 4th. Mercury is either inadmissible, or not required, or even dangerous, for phagedænic and sloughing chancres, and in the other circumstances above noticed (§ 129); 5th. The longer a syphilitic sore continues unhealed and secreting the contaminating matter, the greater the risk of constitutional infection; 6th. The more robust the constitution, and the more perfect the general health, the risk of secondary symptoms from primary sores appears diminished; but this vital resistance to contamination should not prevent the early cure of chancre, more especially when it is indurated, nor prevent a recourse to mercury if the sore has been neglected or of long continuance.

132. Having determined, after due consideration, to have recourse to mercury, the selection of the preparation and mode of exhibiting it require some attention. The preparations which are most suited to the primary disease, when there is no bubo, are the hydrargyrum cum creta and calomel, and in some cases the pilula hydrarg. chloridi composita. The other preparations of mercury, especially the mercurial ointments and the bichloride, are more beneficial in other states of the distemper. The dose, and frequency of exhibiting the hydrarg. cum creta or calomel, require no remarks. They should be regulated according to the state of the patient, and their effects upon the bowels. Calomel generally requires to be conjoined with small doses of opium, or with the pilula saponis composita, but in this latter combination the dose of calomel should be much increased. The object is to produce a slight soreness and sponginess of the gums, with a very slight salivation when indurated chancre exists, and to continue it for four or five weeks, preferring in the latter case the longer period. The dose of the medicine should be regulated according to its effects. During this course the regimen of the patient should in part depend upon his state of health when commencing it. He should live regularly, but not too low. If he be in ill health in other respects, the treatment, and regimen, and diet suited to his state should be prescribed. In

general, excesses in food and wine should be avoided, and whatever is calculated to disorder his digestive and biliary organs. The clothing should be warm; and fatigue, cold, wet, the morning and night air, ought to be carefully avoided. If, notwithstanding this attention to health, and to the prevention of disorder, any of the indications described, when treating of the injurious effects of mercury, make their appearance, the means recommended for their removal, in the articles ERYTHISM, MERCURIAL, and POISONS (§ 562, *et seq.*), should be employed.

[In regard to the use of *mercury* in the treatment of syphilitic diseases, the editor, from a long course of dispensary, hospital, and general practice, has arrived at the following conclusions: 1st. That venereal affections of every description are curable without mercury, and especially all secondary and tertiary forms of the disease; 2d. That the accumulated experience on this point ought to suffice to banish this mineral from the treatment of this class of diseases, except perhaps in some rare cases, when there is hepatic derangement and torpor of the liver, when it may be advantageously given as an alterative, in small doses; 3d. Mercury has no power to prevent secondary symptoms when given in the primary stages; 4th. This mineral, if given freely, will induce, and in all cases increase the tendency to ulceration of the mucous surfaces, especially of the mouth, fauces, palate, and throat, and also cause affections of the bones very similar to those caused by syphilis. The diseases produced by it have very generally been confounded with those produced by the venereal poison; 5th. The symptoms following mercurial treatment are more severe and difficult to remove than those following primary sores not treated with mercury; and, when relapses do occur in the secondary stage, they are far more readily removed in those cases where no mercury has been given; 6th. Mercury, when given incautiously, or in too large quantities, especially in syphilitic diseases, tends to undermine the constitution, to predispose to and aggravate constitutional affections, to increase general irritability, to induce inflammation and ulceration in and destroy the mucous textures, to promote morbid absorption and removal of the fatty, fibrinous, and osseous substances of the system, and to induce synovial, albuminous, and serous accumulations in the respective cavities lined with the membranes producing such secretions; though, given in moderate doses, and with proper care, it may tend to remove such accumulations; 7th. The extent and injury to the soft and bony parts of the system, produced by mercury, are more to be dreaded than any primary or secondary effects of venereal poison; 8th. Mercury is not, therefore, a *specific* against any form of syphilitic disease or virus, and is not essential to its cure; thousands having been easily, effectually, and permanently cured of every form and in every stage of the venereal disease without having taken a particle of mercury; 9th. Mercury should especially be avoided in sloughing sores of the penis and other parts, attended with high inflammation and tumefaction of the parts affected, attended with fever, &c.]

133. *C. Gangrenous chancre*, when it occurs in strong, sanguine, plethoric, or healthy persons, is usually the result of excessive inflammatory action, and requires large vascular depletions, free purging, and afterward opium conjoined with sa-

lines, antimonials, &c. Locally, poppy fomentations, poultices with balsam of Peru, or with turpentine; after the nitric acid lotion, will detach the sloughs. If the ulcer which remains is healthy, and heals, there is no need of mercury; but if it ulcerates, independently of the state of the general health, or if secondary symptoms appear, mercurials should be directed. *Sloughing, gangrene, and phagedæna* of venereal sores are, however, most frequently consequences of an exhausted or broken-down constitution, from intemperance or other causes. In such cases, the application of opiate and camphorated lotions to the sore, of strong nitric acid, if it spread; and opium and camphor, or ammonia, the fixed alkalies and tonics taken internally, aided by a generous diet, beef tea, wine, &c., are indispensable.

134. *D. Phymosis* is sometimes caused either by *balanitis*, or by one or more ulcers under the prepuce. In these cases there is more or less discharge. A chancre is often detected by local hardness and tenderness. If the prepuce be elongated, and cannot be retracted, circumcision may be advisable; but generally it will be sufficient to split the prepuce so as to enable the parts underneath to receive due attention, and the treatment which the character and progress of ulceration may require. The frænum is not unfrequently perforated by a chancre; and it then requires to be divided. In the circumstances now stated, the duration of the chancre, and the confinement of the secretion under the prepuce, increases the risk of constitutional contamination, and requires, unless in very recent cases, a recourse to mercury. A chancre in the urethra requires astringent injections, preferably such as contain the bichloride of mercury, and a course of this mineral if not contra-indicated by the state of the patient.

135. iii. THE NON-MERCURIAL TREATMENT of primary syphilis may be adopted in the circumstances above stated (§ 131, 132), or even in others where it may be considered prudent or advisable to have recourse to means which will improve the general health, and enable the constitution to resist the invasion of the poisonous virus. If there be debility or impairment of the digestive and assimilating functions, tonics, the chalybeates; the preparations of cinchona, or of sarsaparilla, or of guaiacum; cod-liver oil, simple or mediated; the compound decoction of sarsaparilla, with or without iodide of potassium and liquor potassæ, will be found the most deserving of confidence, especially if prescribed appropriately to the circumstances of the case, and if the patient live regularly, and avoid intemperance of all kinds, and all causes of vital exhaustion (§ 118).

136. iv. TREATMENT OF BUBO.—MR. II. COOTE states that he knows of no relation between the occurrence of bubo and the frequency of secondary syphilis; and he believes the idea that a copious suppuration from the groin eliminates the venereal poison to be unfounded. "When swelling of the glands occurs in conjunction with primary syphilis, or is supposed to depend upon the syphilitic poison, mercurial frictions are directed upon the thighs, that the mineral may pass through the enlarged parts." In more chronic enlargements the swelling may be covered by a plaster of the unguentum hydrargyri, or of the unguentum ammoniaci cum hydrargyro. "Leeches are not often required to an inflamed bubo, but they

may sometimes be applied with advantage." The existence of suppuration should not suggest an early recourse to the lancet, as absorption often takes place after the skin has become red or even thin. Absorption of the matter from suppurating buboes does not add, in Mr. H. Coote's opinion, to the patient's danger of secondary syphilis. An opening, when required in a suppurating bubo, should always be made in the long axis of the thigh. If any burrowing of matter occur, particularly in scrofulous persons, who are most liable to buboes, tonics, with a restorative and digestible nourishing diet, are required.

137. The treatment advised by Dr. Druitt and Mr. H. Lee for bubo is very different from that now stated. The former writer remarks that the first indication is to produce resolution of *acute bubo*—"by rest, aperient and saline remedies, low diet, leeches and fomentations. The applications to the chancres must be soothing, and mercury, if being administered, should be at once given up. As soon as the tenderness is relieved, pressure by means of a compress and bandage, or by placing a weight on the part as the patient lies in bed, is useful. Even if matter does form, and does not seem inclined to come to the surface, the iodine paint, cold lotions, aperients, tonics, and pressure will sometimes cause it to be absorbed. But if it increases, and the skin becomes inflamed and shining, a puncture should be made, and the case be treated as any other acute abscess." The chief circumstance deserving notice in this quotation is the abandonment of mercury if it have been already prescribed. My observation in former days has induced me to agree with Mr. H. Coote in a recourse to mercurial inunctions on the thighs, as they produce "a complete effect upon the constitution, and may be used with advantage in cases of chronic bubo, combined or not with primary disease." Suppurating buboes, or solid inguinal swellings, will often disappear under this treatment, which, to be effectual, he advises to be done in the following way: "The patient, sitting before the fire, should rub on the skin at the inner part of the thighs a drachm of the strong mercurial ointment every night, or every night and morning. He should slip on a pair of drawers and go into bed, that the absorption of all that which stains the skin may go on. The patient should not be allowed to wash the part except at intervals, to prevent the skin from being chafed." The introduction of a drachm or two of mercurial ointment into the axillæ when in bed will generally produce the mercurial action when it is required in other circumstances.

138. In cases of *indolent bubo* the indication is to improve the general health, by sarsaparilla, tonics, and the other means advised above (§ 135). For these, change of air, sea-voyaging, removal to a warm and dry locality, and digestible food, are the most beneficial means of cure. The local use of iodine is sometimes of service both in these and in the chronic enlargements of the inguinal glands, but it is not so beneficial as the internal use of the preparations of this substance, which, when used internally, should be combined with either the liquor potassæ, or with either of the carbonates of potash, and be prescribed with other suitable medicines. If *sinuses* form, or if *sloughing* or *phagedæna* occur, or if the ulcers become *irritable* or much inflamed, the means suitable to the case, both internal and external, should be employed.

139. v. TREATMENT OF CONSTITUTIONAL SYPHILIS.—A. Of *secondary Affections*.—It has been contended by some recent writers and stated above (§ 46), that the simple and phagedænic sores are rarely followed by constitutional syphilis, whereas the indurated chancre rarely if ever fails to be succeeded by the secondary disease. Mr. H. Coote disputes these positions, and concludes that secondary symptoms in large proportion ensue after every variety of simple and non-indurated chancre. After primary phagedæna, too, secondary symptoms may be dreaded, and no lapse of time seems to render the patient's constitution free, the secondary disease partaking of the character of the primary sore. "If a person were to have a well-marked phagedænic ulcer, I would not guarantee his not suffering phagedænic ulceration of the throat after an interval of ten years, or even more." Mr. Coote adds, that no one who has primary syphilis in any or in its slightest form can be safely guaranteed from the occurrence of constitutional disease; but if six months elapse after the healing of the primary sore, the patient remaining well, the chances are greatly in his favour that he will escape any further disease. An exception, however, must be made in the case of primary phagedæna.

140. It is often necessary to disabuse the patient's mind of the belief that the syphilitic poison may be destroyed by some specific which will enable him to revert to his former habits. All, however, that can be done is to combat the disease as it appears, and to point out those modes of living which may prevent, although they cannot procure complete security from, the constitutional infection, or certainly remove the contamination when it has already been produced. Much depends upon the patient himself, in respect of the amount of protection which may be afforded him. For anxiety of mind, gloomy ideas, and all irregularities and excesses, and the other concurring causes mentioned above (§ 115–118), will perpetuate the constitutional contamination, and develop its local manifestations, and induce a state of syphilitic cachexia.

141. If venereal eruptions, sore throat, &c., be ushered in, as they often are, by febrile or inflammatory symptoms, aperients, salines, and antimonial diaphoretics will be of service. The diet should be restricted, the patient confined to the house, and the warm bath often resorted to. "When the febrile state has vanished, if the patient has never taken a course of mercury—or if he have been subjected to an imperfect course of it for the primary symptoms—and his constitution is sound, he may take mercury as already directed. If under its use the strength and general appearance are improved, so much the better; but if the patient gets thinner, weaker, and haggard, and suffers from chills and feverishness, or if his ulcers become irritable and phagedænic, it must be given up. The mercurial vapour bath, or the corrosive sublimate in very small doses, and not carried to the extent of affecting the mouth, will often be of great service when the full course of the mineral is inapplicable." (Druitt, *Op. cit.*, p. 189.) The numerous authorities in favour of the bichloride,\* and my own experience

\* Dr. DROZDI, Professor at Halle, prescribes the bichloride as follows: R. Hydrarg. bichloridi, gr. xij. : solve in aque distillatæ q. s. et adde micæ panis, et sacchari albi, aa, q. s. ut fiant pilule co., sing. gr. j. The pills are to be rolled in powdered (anella bark); and on the first day four pills are to be taken (one fifth of a grain); on

of its effects, have rendered me partial to the adoption of it, in preference to other preparations, when a recourse to mercury should be had.

142. The iodide of potassium is often of great service, especially when a recourse to mercury is considered inexpedient or improper (§ 129); or after mercurial remedies have been prescribed without a satisfactory result, or when they appear to have been injurious. It is in these latter circumstances, and especially where a protracted course, or a too liberal exhibition of this mineral has been directed without avail, that the preparations of iodine, especially the iodide of potassium, in due solution and combination, according to my observation, have been most beneficial.

143. The preparations of sarsaparilla, especially the compound decoction, are always productive of great benefit. They may be prescribed either subsequently to a course of mercury or of iodine; or the bichloride of mercury, or the iodide of potassium may be taken with the compound decoction of *sarzæ*, or with the fluid extract or sirup. In some states of secondary syphilis, the muriate or the nitrate of ammonia may be taken in tonic and aromatic infusions, in as large doses as will not offend the stomach; or the nitro-muriatic acids may be tried, either in weak dilutions or in the infusions just mentioned. But in most cases of secondary syphilis, characterized by much debility and loss of flesh, or by anæmia, few means are so generally useful as a prolonged course of the bichloride of mercury in the tincture, or compound tincture of cinchona, in the proportion of half a grain or a grain to the ounce of the tincture, a drachm or a drachm and a half being taken twice or thrice daily in a little water, according to the circumstances of the case. When the throat, palate, or other parts of the mucous surfaces are much affected, this combination, or the bichloride in the sirup or fluid extract of *sarzæ*, aided by gargles containing the bichloride, or by mercurial fumigation, is very frequently efficacious.

144. In cases of indurated chancre of considerable duration, in most cases of secondary syphilis, and generally in tertiary syphilis, analyses of the blood demonstrate a great diminution of red corpuscles, an increased amount of albumen, the fibrin not being materially altered in quantity. These results should not be overlooked, as they indicate the propriety of caution in the exhibition of mercury, and of selecting the mode of exhibiting it now advised; or of adopting the preparations of iodine, and especially the iodide of iron, prescribing it in the sirup of sarsaparilla.

145. During the treatment of constitutional syphilis, it should always be kept in recollection that whatever depresses the vital force or impairs the general health favours the development of the syphilitic contamination and its external

or local manifestations; and that, if the remedies resorted to produce these effects upon the constitutional energies, they will very probably prove more injurious than beneficial. Hence the remedies should be so combined, exhibited, and alternated; and so aided by a regulated diet, and by a healthy, temperate, or warm and dry atmosphere, as to promote the constitutional powers; improvement in the healthy appearance of the patient generally indicating the success of the medicine employed.

146. *B. The local treatment of secondary syphilis* consists chiefly of warm, vapour, or sulphur baths, for the eruptions; of the application of lotions of corrosive sublimate, or ointments containing the unguentum hydrarg. nitratis, or the unguent. hydr. præcipitati albi, especially when the eruptions are severe, or are leprous or tubercular. If itching or irritation be experienced, lotions or frequent sponging the parts with a saturated solution of the biborate of soda in any emollient fluid will generally be of much service. Dr. Druitt states that "for the common excoriated sore throat any soothing detergent gargle will do. When there are ulcers, it is advisable to use gargles of corrosive sublimate; and when the ulcers are indolent they may be touched with the linimentum æruginis. Mercurial fumigation is also occasionally of benefit. It is effected by putting a scruple of red sulphuret, or of the common black oxyde, or twice the quantity of mercury with chalk, on a heated iron, in a proper apparatus, and inhaling the vapour; a heated penny-piece in a tea-cup will answer the purpose.\*

\* Mr. HENRY LEE has given (*Transact. of Med. Chir. Society of London*, vol. xxxix., p. 339) the following directions as to the use of mercurial fumigations:

"Finding from experience that it was the light-coloured oxyde alone which volatilized, and produced its effects upon the patient's constitution, and having reason to believe that the light colour depended upon the presence of calomel, I performed a series of experiments with calomel alone, or mixed in a certain proportion with the gray oxyde. The general result of these experiments has been to satisfy me that, for the purposes of mercurial fumigation, five or ten grains of calomel alone is, in ordinary cases, quite sufficient; and that when the gray oxyde is used, the admixture of a few grains of calomel will facilitate its sublimation and insure its medicinal action.

"Upon making comparative trials with calomel alone and combined with steam, it was found to act more certainly and with greater regularity in the latter case.

"The plan which I have adopted is very simple. Two small lamps are procured in which the methylated spirit (much cheaper than spirits of wine) is used; over the first lamp is a thin metallic plate, upon which the ten grains of calomel are placed; over the second lamp is a small cup of hot water. A small cane-bottomed chair is placed over the lamps, and the patient sits upon it. He is then enveloped, chair and all, in a blanket; at the expiration of a quarter of an hour or twenty minutes he rolls himself up in the blanket and goes to bed.

"For patients to whom it may not be convenient to procure the spirit lamps, the mode of proceeding may be varied as follows: The patient is directed to heat a thick tile in the fire; this is then put into a night-stool, and a gallipot full of warm water placed upon one corner of it. The calomel powder is then sprinkled over the rest of the tile, and the patient sits over it, being enveloped, as before, in a blanket. This mode of applying the vapour is very convenient in cases of affections, either primary or secondary, of the generative organs. It is not necessary in either case that the patient should breathe the mercurial fumes. It is remarkable how soon the patients' systems are brought under the influence of the mercury by this simple means, and, according to my experience, how effectually it acts in cases both of primary and secondary syphilis. Its great advantage, however, consists in the very little constitutional disturbance produced, and in the avoidance of those symptoms of irritation and debility, both mental and physical, which the prolonged internal use of mercury is so apt to occasion. The mercurial action, when the medicine is introduced through the skin, may be continued for nearly any length of time that may

the second day none; on the third day six pills; on the fourth none; on the fifth eight pills; on the sixth none; on the seventh day ten pills, and so on, until the twenty-seventh day, when thirty pills are to be taken (1½ grain). The treatment is then complete, but in some instances of severe secondary symptoms they are to be carried even farther. The pills may be taken on a full meal. Sarsaparilla is also to be taken during the course, or even afterward. Also animal food is to be reduced to one half the usual quantity, and pork and bacon avoided. The cold night and morning air, and cold and wet are to be shunned. I have been consulted by patients for whom this treatment has been adopted, but the cases have been too few to admit of an opinion respecting it. It is merely a modification of the well-known treatment advised by VAN SWIETEN.

When a foul ulcer is seated in the velum, or roof of the mouth, or pharynx, or alæ nasi, an attempt may be made to cheek its ravages, by destroying its surface and edges with acid nitrate of mercury." (*Op. cit.*, p. 190.) The ulcerations at the roots of the nails, or between the toes, are cured by the internal administration of mercury, and the application of a solution of nitrate of silver, from four to ten grains to the ounce of distilled water. When the hair falls off the scalp, the hair should be kept short, and the dilute ointments just mentioned applied, or the means resorted to which are advised in the article on the Hair (§ 32, *et seq.*).

147. MR. H. COOTE remarks that the common warm bath effects but little in comparison with the Turkish bath, which is admirably suited for the chronic stages of secondary syphilitic eruptions,\* and which may now be procured in London. Extremes, or even alternations, of temperature should be avoided; and the regimen and diet should be regulated according to the habit of body, the usual modes of living, and the peculiarities of the case, avoiding too great abstinence on the one hand, and too full living on the other; moderation in all things being always observed.

148. vi. THE TREATMENT OF TERTIARY SYPHILIS.—In this state of constitutional contamination, mercury, if exhibited at all, should be prescribed with great caution, and it ought not to be given if it have been previously resorted to, either in prolonged courses, in large quantity, or in such a manner as to occasion copious salivation, or any of the more unpleasant effects described in the article POISONS (§ 562, *et seq.*). But if the patient have not had recourse to this mineral in any form, if none of the more severe tertiary affections exist, the bichloride of mercury may be prescribed in full and increasing doses in the compound decoction of sarsaparilla upon a full meal, or as advised by VAN SWIETEN, or mercurial fumigations may be resorted to. But if a manifest improvement in health, and in the local affection, in a reasonably sufficient time be not observed, or if there be any aggravation of symptoms necessary, and may be repeated as often as may be convenient without injuring the patient's constitution.

"The small quantity of calomel which it is requisite to use at each fumigation is probably one reason why mercury in this form may be used with such comparative impunity."

\* Mr. COOTE describes this bath as follows: "The clothes having been removed, and a suitable bathing-dress supplied, the bather is conducted into a heated apartment, where he is allowed to sit and accustom himself to the increase of temperature. During this time the body becomes covered with a tolerably profuse perspiration. Next he is conducted to another apartment, where there is a higher degree of heat (115° F.), and the atmosphere is charged with watery vapour. There he reclines on a heated marble slab, and undergoes a slow process of shampooing. The quantity of cuticle that peels off surprises one who has not witnessed the process, but the skin is left in a cleaner state than perhaps it had been in for years. After the movements of the limbs have been tested in a variety of ways the bather is conducted to a recess, in which is a fountain with hot and cold water, where he may apply soap and hot water as his taste dictates, or have the process performed by an attendant. A feeling of languor, not by any means unpleasant, supervenes, which renders a short period of repose on a couch agreeable. This process removes a large quantity of cuticle from the integument, causes the blood to circulate through the minute capillaries, and brings into activity the sudoriparous and sebaceous glands. We may, I presume, infer that without the proper performance of these functions the skin is not in a healthy state; and that any morbid condition, such as lepra or lichen, would be materially benefited by rousing them into activity." (*Op. cit.*, p. 103.)

toms from this treatment, the iodide of potassium should be substituted, and given in doses of three grains thrice daily, increasing them to five grains conjoined with the liquor potassæ, or with either of the carbonates. In cases where mercurials have been freely employed, and especially where there is reason to infer that the affection of the periosteum or bones has been caused or aggravated by these medicines, or where there is doubt whether or no any of the tertiary affections have been caused as much by mercury as by the fixed temper, the decided use of the iodides of the fixed alkalies is generally the most beneficial. In cases manifesting more or less anæmia (*see* § 143, 144), the courses of iodides, and still more those of mercury, should be followed by a course of the iodide of iron taken in sirup of sarsaparilla.

149. If the periosteum or bones be diseased, still greater caution in having recourse to mercury is required, although in strong constitutions, and where mercury has not been previously given, full doses of calomel and opium, or of these with camphor, will often initiate the treatment with benefit, and they may be continued or modified as long as they continue of service, and afterward the iodide may be prescribed, increasing the doses until success result from it. I have generally prescribed this medicine in the following combinations:

No. 378. R Potassii Iodidi, ℥j. ad ℥ij.; Liquoris Potassæ, ℥ij. (vel Potassæ Bicarb., ℥ij.); Tinct. Aurum (vel Cascariæ), ʒvi.; Extr. fluidi Sarzæ, ʒss.; Infus. Gentianæ Comp. ad ʒviij. M. Fiat Mist. cuius capiat cochl. ij. vel ij. larga, ter in die in aquæ cyatho amplo.

150. It will generally be of service to take the iodide in weak solutions, even when it is prescribed in the largest doses. If it relax the bowels, a few drops of tinctura opii, or a little tinctura camph. comp. may be added to each dose; or the iodide and the alkalies may be taken in the compound decoction of sarsaparilla, to which a tonic or aromatic tincture, or an opiate, may be added, according to circumstances. When this remedy succeeds in removing the venereal affection, it should be continued for some weeks afterward, gradually diminishing the dose. In some cases it causes irritation of the mucous surface of the throat, nostrils, and eyes, with a copious defluxion, or pains at the region of the stomach, or irregular febrile symptoms. These disorders are observed especially when the iodide has been given in too large doses, or uncombined with the carbonate or solution of potash. When taken thus uncombined, the acid in the stomach decomposes the iodide, and the free iodine irritates the mucous surfaces.

151. In cases of ulceration of the pharynx, or larynx, or of disease of the bones, of the palate or nose, mercurial fumigations may be first tried, if mercury has not been already employed; but care should be had not to allow it to affect the mouth. Sarsaparilla, with a cautious use of the iodide of potassium and sedatives; the application of a strong solution of the nitrate of silver, or of the bichloride of mercury to the ulcerated surface, and of terebinthinate embrocations to the throat externally, are often beneficial. Gargles containing either the bichloride or the iodine, neither of these substances being in such quantity as to occasion much irritation of the throat, may also be tried. In all these the utmost attention and care are required. When tuberculated or other eruptions assume the characters of open sores or ulcers, the simple or compound

tincture of iodine will be most advantageously applied to them, in modes and in degrees of dilution varying with their appearances.

152. When nodes are formed, the pain and consequences which often result require iodine, alkalies, sarsaparilla, and opiates, with light, nutritious diet, residence in a warm and dry air, and blisters over the affected parts. The blisters often should be repeated, in order to prevent, by the external discharge, the inflammation from extending to, or disorganizing the osseous structure. If mercury have not been employed, the blistered surface may be dressed with strong mercurial ointment, and either with opium or morphia; and the diet and regimen duly regulated, with strict reference to the several peculiarities of the case, to the extent to which the general contamination and cachexia may have advanced, and to the state of the local affections.

153. vii. SYPHILIS IN INFANTS AND CHILDREN. —The treatment should be directed not merely to the infant or child, when the state of either admits of any hope from treatment, but more especially to the parents. For these as well as for the child, a mercurial course, if not previously had recourse to, should be prescribed; and in the majority of cases, the bichloride of mercury, exhibited as above (§ 141), or combined with either of the tinctures of eichona, will be found the most efficacious. Subsequently the iodide of potassium or iodide of iron, and the preparations of sarsaparilla may be employed, according to the peculiarities of the case, more especially if anæmia be very manifest. It has been recommended for children to rub ten grains of mercurial ointment, daily, into the axilla or soles of the feet, or to administer half a grain or a grain of hydrargyrum eum creta every night until the symptoms disappear. But the disease is not so completely eradicated by these means as by a judicious exhibition and management of the bichloride, especially when followed by the means just named, varying the dose, and the vehicle in which it is prescribed, with the age and circumstances of the case.

154. X. SYPHILIZATION, or the inoculation of syphilis, has recently attracted attention not only as a cure, but as a prevention of any future occurrence of the distemper.—i. HISTORY.—M. AUZIAS TURENNE first proposed this startling mode of treating and of preventing syphilis in 1850, by bringing it before the French Academy of Medicine. This young physician commenced, about 1844, a series of experiments with the view of testing JOHN HUNTER'S doctrine of the non-communicability of syphilis to the lower animals. After many experiments and some failures, he succeeded in producing in monkeys, inoculated with chancre-matter, a true chancre, and the disease thus communicated to them was transferred to rabbits, cats, and horses. "The malady was again returned by inoculation from these to the human species, the first trials in this regard having been made by Dr. ROBERT WELTZ, of Würzburg, on his own person. On four separate occasions Dr. WELTZ succeeded in producing an unmistakable chancre on his own person, by inoculation from animals, and this was acknowledged even by RICORD."

155. This discovery, as stated by Dr. RADCLIFFE, issued in one more surprising still, upon which the process of syphilization is founded, namely, the strange and curative change of the

disease when the inoculations are often repeated in the same individual. Experimenting upon apes, it was found that the artificial ulcers regularly diminished in size and virulency, in proportion as the inoculations were multiplied, until at length the virus ceased to take effect. The system seemed to become protected, as in ordinary inoculation and vaccination, and a state or diathesis was produced in which the body was no longer capable of being affected by syphilis; and the process by which this is accomplished is that to which the name *syphilization* belongs. This result, also, is all the more surprising because reiterated inoculations were evidently essential to it, for only once inoculated and then left to themselves, the poor apes speedily perished with all the signs of the syphilitic cachexia. Having satisfied himself of the reality of these results, M. AUZIAS TURENNE then proceeded to inquire whether man was capable of syphilization. He had many ardent followers, who eagerly submitted to the experiment, and who shortly seemed to furnish evidence in the affirmative.\*

156. This pretension excited great opposition, particularly in the Académie de Médecine. In other quarters, however, the impression was more favourable. At Turin, M. CASIMIRO SPERINO, the chief surgeon in the Syphiliticoma, or Syphilitic Hospital of that city, at once took up the new views, and put them to the test on a large scale. He was favourably inclined towards them, he tells us, for several reasons. He had observed that severe inguinal buboes are more apt to follow small and insignificant chancres, which heal in a few days, than those which are large and obstinate; that the constitutional symptoms held an almost inverse relation to the severity and continuance of the local disease; and that he had known many prostitutes, whose constitutions had never been sensibly affected, who had had chancres for years, either constantly open, or closed only to open again immediately. He had repeatedly satisfied himself that foul buboes were more prone to heal in those cases in which their syphilitic character had been tested, after RICORD'S plan, by inoculations on the surrounding skin.

157. The subjects of M. SPERINO'S experiments were fifty-two hospital patients, all prostitutes, and all suffering from aggravated forms of primary or secondary syphilis. The virus was taken from the person syphilized, or from a comrade—from the first, if possible—and always from a growing ulcer. The inoculations were repeated once or twice a week in three or four distinct places, usually in the abdomen. The time required for the establishment of the artificial chancres was from two to three days. The effects of the second inoculations were less serious than the first; of the third, than the second; of the fourth, than the third, and so on until the virus ceased to produce any effect whatever; contemporaneously with which epoch, all former ulcers had healed, and buboes, recent nodular enlargement of bones, and cutaneous stains or blotches,

\* In Dr. WINTERBOTTOM'S work on the native Africans already referred to, it is stated, on the authority of Mr. EDWARDS, the author of the "*History of the West Indies*," that the natives of the Gold Coast of Africa give their children the *yaws* by inoculation, and that they perform the operation by making an incision in the thigh and inserting some of the matter from the sores of the yaws. By this means the infants or children have the disease slightly, and recover speedily; whereas, by becoming infected at a later time of life, it is much more severe, and "gets into the bone." (Vol. ii., p. 156.)

had either disappeared, or were in rapid process of disappearance. The virus, also, which made no impression at this time, was found to retain all its virulence when tried upon an unprotected person.

158. Since this time M. SPERINO has shortened the intervals between the several inoculations, and has increased the number of punctures in each operation to twelve, sixteen, or twenty, and with the effect (he tells us) of expediting the process, and of ensuring a slighter form of artificial chancre. He has also subjected his syphilized patients to a course of bathing in the sulphureous waters of Acqui, which waters are notorious for their power of bringing out secondary symptoms in the subjects of syphilis, and he has found them to resist this test as well as that of inoculation.

159. Such are the main particulars of these fifty-two cases, as gathered from M. SPERINO's communication to the Academy of Medicine and Surgery at Turin. No other treatment was employed. They are said to have been without exception of an aggravated character, and without any spontaneous tendency to heal. For a month before the institution of the experiments they had been purposely left without any treatment, and during this period they had retrograded.

160. An account of Dr. SPERINO's proceedings was given by Dr. RADCLIFFE (in RANKING's *Abstract of the Medical Sciences*, vol. xvi., p. 333), and M. TURENNE's experiments were noticed by Dr. DE MERIC (*Lancet*, July, 1853, p. 203) before Dr. SPERINO's work had appeared. The subject has been very recently brought before the profession in an able article on syphilization in the "*British and Foreign Medico-Chirurgical Review*" (No. xxxvii., p. 410), in which the subsequent experience of Dr. SPERINO in Turin, of Professor BOECK in Christiana, of Dr. DANIELSEN in Bergen, and of Dr. CARLSSON in Stockholm, during several years, has been given. These enlightened men, professors and physicians to hospitals in cities where medical science is in its highest state of rational cultivation, instead of declaiming against the doctrine promulgated by M. A. TURENNE, have been engaged in a series of careful experiments and observations to determine its truth or its fallacy. Experiment and careful observation can alone decide this question, which is one of the greatest importance in practical medicine.

161. Dr. SPERINO's observations were confirmed by similar results obtained by Dr. GAMBERINI at Bologna, and by Dr. GULLIGO at Florence. In 1853, Dr. SPERINO published a detailed account of ninety-six cases of syphilization. Of these ninety-six cases, fifty-three were of primary syphilis, and forty-three of the constitutional disease. Fifty of the cases of primary syphilis were cured, two failed, and one was not treated by syphilization alone. "Of the forty-three cases of constitutional affection, twenty-six were treated by syphilization alone, and seventeen by this method, in conjunction with mercury or iodine. Twenty-five of the twenty-six in the first category are said to have been cured. In only two cases of the primary disease did any constitutional symptoms appear, and these symptoms rapidly yielded under a continuance of the syphilization. No relapse has yet taken place in any case. Many of these cases were of very severe character, and were such as were not likely to have healed spon-

taneously; while the numerous inoculations that were required produced no serious effects, except in one or two instances a slight tendency to form phagedenic sores."

162. Dr. BOECK, of Christiana, in 1853, published, in the seventh volume of the Norwegian Medical Journal, the results of a few experiments he had then made on syphilization. Since then he has closely investigated the subject, and has extended the practice to infants at the breast. The same plan of treatment has also been pursued by Dr. DANIELSEN in the hospital at Bergen. When the writer of the review above referred to (§ 160) revisited this hospital in July, 1856, he was assured by this physician "that he fully coincided with the views of Dr. BOECK, and that the results obtained in Bergen by syphilization were as successful as those recorded by the latter at Christiana." The reputation, talents, and high position of those physicians in Norway are unquestionable.

163. Dr. BOECK states that all the cases which he treated by syphilization laboured under constitutional syphilis, in its most varied stages and forms. Some of those cases had previously undergone every mode of treatment that science could devise, while others had had no treatment at all. He thought it of great importance to collect observations from both classes of cases. If syphilization is not had recourse to till all other remedies have been tried, it is difficult to form a correct estimate of its powers; for under such circumstances, as Dr. BOECK justly remarks, we can hardly know what symptoms belong to syphilis, and what to the medicines administered; and particularly to mercury. He states that cases which have undergone a mercurial treatment, persons of an inflammatory diathesis, habitual spirit drinkers, and weakly constitutions, should not be subjected to this treatment. In these cases the artificial chancres may take on a malignant action. "The bowels should be regulated, and the digestive organs brought into good order; but it is not necessary to enforce any strict rule of diet. In the hospitals of Bergen and Christiana the ordinary full diet was always allowed." Dr. SPERINO and Dr. BOECK mention the readiness with which patients submitted to, and even sought for, the mode of cure which they had seen so successful with their fellow-sufferers.

164. ii. MODES OF INOCULATION.—M. A. TURENNE at first kept up a succession of single chancres; while SPERINO made three or four separate inoculations at once, and repeated these two or three times in the week. After having in this way reached twenty-four or thirty inoculations in all, he found that the chancres last produced were exceedingly small, and he then diminished the intervals, and made more inoculations at each sitting. He found that the first chancres were deeper, larger, and more inflamed than those which succeeded them; and that by diminishing the intervals and increasing the number of inoculations the earliest chancres visibly diminished, and were less painful and inflamed. After a large number of inoculations which did not appear successful, he returned to his former plan of inoculating for six to ten chancres at a sitting. "While these chancres are progressing, it is not advisable to inoculate afresh, nor should this be done until the former chancres are developed. Should the chancres be developed too freely and threaten active inflammation, or to extend

as phagedænic sores, he checks their progress by inoculating afresh at shorter intervals."

165. The practice of Dr. BOECK differs little from that of SPERINO. He inoculates for two chancre only every six days, because he found from experience that it required about five days to produce induration in a chancre, although he does not consider this latter circumstance absolutely essential. He subsequently shortened his intervals to three days, and increased the inoculations to eight or ten. Less time is thus required to produce immunity; but Dr. BOECK is distrustful of pushing cases too rapidly through their course of syphilization. With regard to the parts of the body selected by these physicians for inoculation, SPERINO preferred the lower regions of the abdomen, Dr. BOECK the arms and thighs.

166. The conclusions drawn by Dr. BOECK from the eighty-four cases of syphilization, which he has treated up to March, 1856, are: 1st, that in all cases, without exception, immunity to the venereal virus is obtained, sooner or later, by inoculation of the poison; 2d, that the symptoms of syphilis present at the commencement of syphilization disappear during the employment of this mode of treatment; 3d, that the general health does not suffer in the least from syphilization; on the contrary, if the patient has been in weak health before inoculation, he most materially improves in strength and appearance during the process. These propositions are conceded as undoubted facts by Dr. BOECK's colleagues, by Dr. SPERINO, by M. A. TURENNE, by DANIELSEN, by Dr. CARLSSON, and by Dr. STENBERG of Stockholm.

167. *The time required to produce immunity from syphilis by syphilization depends upon the various strength of the virus, upon the rapidity or otherwise with which the inoculations succeed each other, upon the number of the chancres produced, and upon the idiosyncrasy of the patient.* Dr. BOECK states that "the attaining to immunity depends upon the length of the intervals between each inoculation—the more frequent the inoculation the more rapidly does it ensue. If there were sufficient virus to be obtained, we might, if we chose, inoculate every day; but if, as is generally the rule, we keep to obtaining the virus from the most recent inoculation, we cannot easily do this. From my own experience, I would say that the matter obtained in a pustule of only one day's growth is generally capable of being inoculated; but I have also seen that pustules of three days' growth produced no effect; while three days later, the matter taken from them was decidedly contagious." (P. 196).

168. Granting that immunity is really produced from the disease, the question follows, Is it merely from the existing disease, or from any subsequent infection? and if from subsequent infection, is the immunity, produced for a time only, becoming impaired gradually, and ultimately lost after an indefinite time; or is it continued through life, a diathesis being imparted by it, rendering the frame insusceptible of the syphilitic infection? \* That the immunity is at least for a

time, is shown by the fact of the last inoculation having failed to take effect, however virulent the matter employed. Dr. BOECK is of opinion that persons who have reached perfect immunity to inoculation in the course of syphilization are insured against contracting syphilis for all the rest of their lives; but the lapse of time since the first employment of this practice admits not of any conclusive evidence of the fact.

169. Of forty-two cases of constitutional syphilis, where no mercury had been previously used, not one had exhibited any relapse up to the commencement of 1856, and many of these had been for three years or more without requiring any treatment whatsoever. Of the twenty-one cases recorded in Dr. BOECK's first work, six had been treated without mercury, and in all these syphilization dispersed the symptoms, which have never returned. The average duration of the treatment in these six cases was six months and two days, the average number of chancres were 322. In a second class of cases, in which the constitutional symptoms were chiefly confined to the skin and mucous membranes, but which had all taken more or less mercury, the average duration of treatment was six months and twenty-four days, the average number of chancres being 432; two thirds of the number being, however, very small and transient. In the third category of cases, in which the constitutional disease was very inveterate, all of which had been subjected to mercurial treatment, some repeatedly, the average duration of treatment was seven months and twenty-four days, the average of chancres 570.

170. The increase in both of the last categories of cases in the number of chancres, and in the length of time required to complete the cure, is ascribed by Dr. BOECK to the previous administration of mercury. It is, however, probable, as he observes, that another circumstance may have retarded the cure, viz., that the syphilitic virus may have undergone a material change during the many years it had been resident in the system. The more inveterate, and especially the tuberculo-serpiginous forms, were found to be extremely rebellious to treatment, and some of them were not cured when immunity was reached. It was necessary then to have recourse to iodine, upon the exhibition of which all symptoms rapidly disappeared, though previous to syphilization both mercury and iodine had proved inefficacious.

171. Dr. BOECK suspects that in those very obstinate cases a union of the syphilitic with mercurial poison has taken place. In most instances this union seems to be dissolved by syphilization, and then iodine, which had before been ineffectual against the united poisons, acts readily on the mercury, and eradicates it from the system. During the two years elapsed from the publication of his first work, he had treated sixty-three cases by syphilization, and of these thirty-six had never taken mercury. In the twenty-seven cases, for which mercury had been given, he invariably found the cure more difficult, and in some cases impossible without the aid of iodine. Where

\* "I am much inclined to believe," says Dr. BOECK, "that this is really the case, but to prove it is not so easy; for, according to my views, this question cannot be determined by artificial inoculation. I have not considered myself justified in putting those healed by syphilization to the proof of inoculation after some time had elapsed since the cure, as I thought it possible that such inoculation might produce constitutional symptoms, as I

believe that syphilization *destroys* the syphilitic poison in the system. RACON's dogma, that an individual can only once in his life be affected with constitutional syphilis, may perhaps be erroneous, and the patient might then be in the position of a previously healthy person newly inoculated with syphilis. I have, therefore, always abstained from testing by inoculation those who had not previously been treated with mercury."—*Med. Chirurg. Review*, Apr., 1857, p. 321, Am. ed.]

mercury has not been employed, he is decidedly in favour of syphilization, for, as far as can be ascertained from the forty-two cases of this character thus treated, no relapse had occurred up to the present period. A great objection to syphilization is the length of time required for its complete performance. In the Christiana hospital, the average duration of the mercurial cure is three months and a half, while syphilization averages a full half year. If, however, the latter be not liable to relapse—at least in non-mercurialized cases—it is preferable, even if it required a much longer period. It is doubtful whether it is possible to syphilize, so as to cure permanently, by matter taken from one source alone; for Dr. Boeck met with cases where complete immunity existed to the matter taken from one source; but upon obtaining fresh virus from other persons, the inoculation succeeded perfectly again. However, he has been able, in some instances, to effect a complete and permanent cure with matter from one source alone.

172. I have given this account of syphilization, as it is hardly known in this country. It is manifest that it could not be rationally submitted to, but as a cure of the distemper, and not by a healthy person to prevent the infection of it. If, however, it be found to be by farther experience, not only a permanent cure, but also a permanent preventive, it will establish for itself a reputation not possessed by any other means; for none besides, however judiciously administered, has been found constantly and permanently curative—has proved a remedy under all circumstances, and for the future duration of life in all cases.

- [AMER. BIBLIOG. AND REFER. — *John W. Francis*, an Inaugural Dissertation on Mercury, embracing its Medical History, Curative Action, and Abuse in certain Diseases. N. York, 1811; also, an Essay on the same subject in Amer. Med. and Phil. Register for April, 1813, and April, 1814. In this Essay Dr. F. condemns the practice of giving large quantities of mercury for the cure of syphilis, and especially the practice of inducing salivation at that time generally supposed necessary for the cure of the disease, and advocates the use of small doses of *corrosive sublimate* in connexion with the free employment of a decoction of guaiac and sarsaparilla, drunk warm. The advantages which he claims for this mercurial preparation over all others are that, if judiciously administered, it is particularly mild and safe in its operation, will admit of a more extensive use in all the various forms of the disease, and subject the patient to fewer inconveniences; that it readily enters the circulation, and soonest arrests the progress of the complaint by eliminating the morbid matter from the system; that it supercedes the necessity of salivation by its action on all the secretions, and especially those of the skin and kidneys; that it is the only preparation to be depended on in those peculiar habits of body so susceptible to salivation by every other form of mercury now in use; and, lastly, that in its ultimate effects on the constitution it is attended comparatively with no injury. Dr. F. recommends it to be given in doses of one eighth of a grain twice a day la pill, after the following formula: R *Oxymercurii, Hydragr. Murat. Ammon.*, aa, gr. xv.; *Aque destillat.*, jss.; *Panis q. s.*, ft. pil. exx. To children he recommends it to be given in a state of solution, two grains to one ounce of brandy, of which three or four drops may be given in sweetened water to a child of one year, and repeated three times a day; and to a child of two or three years old, six or eight drops three times a day, increasing the dose after two or three days to ten or twelve drops. This mode of treating syphilitic affections was introduced into the New York Hospital in 1811, and about the same time into the New York Alms-house and City Dispensary, and, according to Dr. Francis, with marked success compared with former modes of treatment. He advises that the medicine should be continued two or three weeks after the disappearance of the disease, in order more effectually to accomplish a radical cure. The decoction of guaiac and sarsaparilla are to be prepared by boiling an ounce of each in three pints of water to two pints, of which the whole is to be drunk warm in the course of twenty-four hours. (Dr. Harris states that he had not used mercury in the treatment of any forms of this disease for the last six years, during which time he attended 164 cases of venereal. He treated it by bleeding and purging, the warm bath once a week, and the "decoction of the woods." Secondary symptoms rarely appeared; in two cases of the latter, nitric acid and the above decoction were entirely successful. Twenty-three other secondary cases, which had been treated with mercury by other practitioners, were effectually cured without it. The local treatment consisted in poultices and cooling lotions, if there was much inflammation; afterward the black wash, a strong solution of blue vitriol and the nitrate of silver, where a stronger caustic was indicated.)—*John Bell*, a Treatise on Baths; including Cold, Sea, Warm, Hot, Vapour, Gas, and Mud Baths, &c., 12mo, p. 653. Phil., 1850. (Dr. Bell gives a very favourable account of the influence of the Vapour Bath in Syphilitic Eruptions and Ulcers, also of sulphurous fumigations; he also gives a history of mercurial fumigations, and baths of corrosive sublimate for the cure of venereal affections, which the reader may consult with advantage.)—See also "Lectures on the Theory and Practice of Physic, by John Bell and William Stokes," 2 vols., N. York, 1845. (Dr. Bell advocates the non-mercurial treatment, and says, p. 567, "I can speak confidently, after positive experience, of the success attending the use of iodine in tincture, and of the *iodide of potassium*, with the compound sirup and decoction of sarsaparilla in cases of venereal disease, both of the tonsils, and mouth, and tubercular ulcerations, after mercury had been prescribed by

those who preceded me in vain.")—*Grover Coe*, "Concentrated Organic Medicines; being a Practical Exposition of the Therapeutic Properties and Clinical Employment of the combined proximate medicinal Constituents of Indigenous and Foreign Plants," &c., 8vo, p. 431. N. Y., 1853. Of the indigenous plants recommended for the cure of syphilitic affections, the most important are: *Smilacin*, the active, neutral principle of the *Smilax officinalis*, in doses of two grains three times a day; the concentrated Tincture of *Smilax sarsaparilla*, in doses of fifteen drops; *Menisperm*, derived from the *Menispermum Canadense*, in doses of from two to five grains, three times a day, especially for the train of symptoms termed *Mercurio-syphilitic*; *Xanthoxyl*, derived from *Xanthoxylum fraxinum*, in doses of from two to four grains, including the Oil and concentrated Tincture of *Xanthoxylum*, in doses of from two to five drops each; *Hydrastin*, from *Hydrastis Canadensis*, in gleet and gonorrhœa in doses of one or two grains three times a day; *Irisin*, from *Iris versicolor*; *Corydatin*, from *Corydalis formosa*; *Stillingin*, from *Stillingia sylvatica*; *Phytolacin*, from *Phytolacca decandra*; *Rumin*, from *Rumex crispus*; *Alwin*, from *Alnus rubra*, Swamp Alder; *Podophyllin*, from *Podophyllum peltatum*, May-apple; *Chimaphillin*, from *Chimaphilla umbellata*; *Ampelopsin*, from *Ampelopsis quinquefolia*; *Macrotin*, from *Macrotis racemosa*. The actual value of the above remedies, in the various forms of syphilis, is to be determined by farther observations and more extended experience. There is good reason, however, to believe that among them will be found some of the most valuable alternatives in the Materia Medica, and good substitutes for the foreign sarsaparilla, guaiac, mezereum, &c.]

VERTIGO.—*SYN.*—*Vertigo* (from *verto*, I turn round); περιστροφή, σκότωμα. *Vertige*, Fr.; der Schwindel, Germ. *Giddiness*, *dizziness*, *swimming in the head*.

CLASSIF.—IV. CLASS, III. ORDER (*Author*).

1. DEFIN.—*A transitory erroneous perception, or a sense of general whirling or turning round, with difficulty of standing, or a feeling of impending sinking or falling.*

2. *Vertigo* has been noticed by HIPPOCRATES, GALEN, ARETÆUS, and other ancient writers; and by these, as well as by modern writers, it has been viewed chiefly as a symptom of many diseases, and in some, but in much rarer cases, as the chief or only apparent disorder. That it is as much a primary affection, on some occasions, as headache, or several other disorders, may be admitted, although it may be shown, if the pathogeny of the affection be duly considered, that it is commonly owing to previous disorder of the organic nervous influence endowing the brain, or to the state of the capillary circulation in this organ, or not improbably to both in various degrees. In the great majority of cases, however, it is merely a symptom, either of a very early, or of a more or less advanced stage of some malady, very often of some disease which has not fully declared itself, or which still remains latent or imperfectly developed, or of extreme debility, or of protracted indigestion, &c.

3. I. DESCRIPTION.—*Vertigo* occurs as an illusion, or a transitory erroneous perception of objects, although quiescent, in a state of more or less rapid motion, usually in that of gyration or whirling round; but also not unfrequently with either a descending or ascending movement, or with a sense of sinking. In the more extreme cases, or when caused by ebriety, these sensations are often present in a greater or less degree, although the eyes at the time are quite shut. In some instances the objects which thus appear in motion are also changed in colour—are either variegated or obscured. *Vertigo* may be experienced only when assuming the erect posture, as in cases of fever, extreme debility, &c.; but it may also be felt while recumbent in bed, objects presenting not only a rotatory, but also an ascend-

ing motion, with a feeling of sinking, and sometimes also with noises in the ears. In this latter form it should be viewed as a most serious symptom, especially when occurring in malignant or pestilential maladies, or when these are prevalent, or in the course of organic disease of the brain. In many instances, vertigo precedes, or is followed by, severe paroxysms of retchings or of vomitings. This sequence is commonly observed in pestilential cholera, in sea-sickness, in fits of drunkenness, after ingestion of the sedative or depressing and irritating poisons, and especially after the improper or inordinate use of tobacco. In all cases of vertigo, walking or even standing is difficult or impossible; and, from a dread of falling, objects are laid hold of for support. Vertigo may be only temporary and quickly evanescent, or it may continue for a considerable time. It is more rarely continued or prolonged. It is often evanescent, but marked, when it occurs as a prelude of syncope, or of fully-developed disease of the brain, as epilepsy, paralysis, or apoplexy. It often precedes amnesia and other states of insanity. SWIFT was very subject to vertigo at different periods of his life, and more especially before the loss of his powerful mental faculties. It is more prolonged or continued when it is a symptom of either active or passive congestion of the cerebral vessels, or of anæmia of the brain, or of the vascular system generally. When vertigo occurs as a severe or acute paroxysm, it may gradually pass into the epileptic state; the extreme giddiness, after several occurrences of the seizure, being attended by a temporary loss of consciousness, and ultimately by convulsions and all the phenomena of a complete epileptic attack.

4. The more continued or prolonged states of vertigo are generally referrible to the following pathological conditions: 1st, to determination of blood to the brain; 2d, to congestion of blood in the cerebral vessels, owing to impeded return of blood or retarded circulation through the heart; 3d, to lesions of the cerebral arteries, and softening of the structure of the brain; 4th, to general or local, momentary or prolonged anæmia, or insufficient supply or circulation of blood in the brain. In these states, however, one or other of the primary changes already assigned as characterizing the more evanescent states of the affection (§ 3) are also present. In either of these forms, or owing to either of their pathological states, vertigo may manifest certain grades, either of which only may be complained of, or all of which may supervene in succession, either very slowly and imperceptibly, or more or less rapidly. These states or grades are usually described as, 1st, confusion, unsteadiness, or indistinctness of perception; 2d, dizziness or fear of falling; 3d, giddiness, with incapacity of progression; and, 4th, swimming in the head, or complete vertigo, with an incapability of standing.

5. i. *The occasional exciting causes* of vertigo are very different, or even opposite in different cases. Whatever determines the blood inordinately to the brain, as long and intense thought and reflection; or prevents and impedes the return of blood from this quarter, as cinetures of the neck, &c.; and whatever promotes a rapid return of blood from the brain, as suddenly assuming the erect from the recumbent posture, long abstinence, inanition; and, in short, whatever occasions too great fullness on the one hand, or too great a deficiency of blood in the brain on the

other, will, in weak, susceptible, or predisposed persons, give rise to this state of morbid perception.

6. Vertigo is most frequent in persons of advanced age, in hysterical females, in persons who are bald, especially on exposure to cold, or in cold seasons and in variable weather; in those liable to hæmorrhoids, epistaxis, or other hæmorrhages, especially when these are suppressed, and in crowded and close apartments; in females during prolonged lactation; in persons addicted to excessive sexual intercourse, or to the vice of masturbation; and in those who indulge in too much sleep, or who lie too long in bed, or who live irregularly as to diet and regimen.

7. The more common causes of vertigo are obviously those which produce the diseases of which vertigo is a more or less prominent symptom; while those occurrences of it which assume more of a primary or idiopathic form, are referable entirely to whatever occasions the pathological states of which it is a chief manifestation. Thus, if it be imputed to vascular determination to, or congestion of blood in the brain, the numerous remote and efficient causes of these conditions should be ascertained, as indicating the only obvious means of removing the affection. If it be chronic, protracted, or of frequent recurrence, the temperature of the scalp, the state of the arterial and venous circulation in the neck, temples, &c., the circulation through the heart; the functions of the stomach, bowels, and kidneys, &c., severally require examination, especially with reference to excessive or to deficient fullness of blood in the vessels of the brain. The causes of these very opposite conditions are generally manifest on due investigation; but these conditions are commonly attended by others of not less importance, namely, by excited or by depressed vital power—by the latter especially. This association of disordered circulation with depressed vital power obtains in most cases of this affection, whether protracted or evanescent; and in febrile diseases the blood is also more or less altered, although not in a manifest degree at an early stage of these diseases. The impairment or depression of vital power is especially evinced by the organic nervous system, through the media of the several organs which this system endows, and more particularly of the digestive, assimilating, and generative organs. Impairment of the former, and exhaustion from abuse of the latter, are among the most efficient sources of this affection, in its more chronic forms. When it proceeds from this last source, the disorder is often most protracted and most difficult to cure, for the cause generally continues; and it not unfrequently assumes a recurrent or periodic form, and even ultimately, but gradually, passes into fully-developed epilepsy, or the worst forms of hysteria. Of these results I have seen several instances in both sexes, in the course of my practice.

8. ii. *The chief states and associations* of vertigo may be enumerated as follows, with reference to their causes: 1st. *Vertigo nervosa*: nervous, hysterical, epileptical, or hypochondriacal vertigo. 2d. *Vertigo traumatica*, from injury, concussion, &c., of the brain. 3d. *Vertigo plethorica*, from determination of blood to, or inflammation or active congestion of, the brain. 4th. *Vertigo toxicata*, from poisons, especially sedative and narcotic poisons, and from poisonous fish, meats, &c. (See art. Poisons.) 5th. *Vertigo febrilis*,

in the invasion and progress of most fevers, especially when the organic nervous force is depressed, and the blood contaminated. 6th. *Vertigo gastrica vel Stomachica*, from gastro-bilious disorder; such disorder, however, often being, as well as the vertigo, merely symptomatic of disease of the brain. 7th. *Vertigo exsanguinea*, from an insufficient supply of blood to the brain, or from general anæmia, or unequal distribution of blood. 8th. *Vertigo cardiaca*, from disease of the heart impeding the return of blood from the brain. 9th. *Vertigo arthritica*, from misplaced or retrocedent gout. 10th. *Vertigo rheumatica*, from rheumatism of the membranes of the brain, or of the pericranium. 11th. *Vertigo accidentalis vel fugax*, from various odours or smells, especially in certain idiosyncrasies, or from various causes, often of an indefinite or not very manifest nature.

9. iii. *The Diagnosis and morbid Relations of Vertigo*.—The nature of the affection is generally manifest from the account given by the patient of his sensations. It may, however, in the more sudden attacks, be mistaken for a slight seizure of either apoplexy or epilepsy. From both these it may be readily distinguished by the loss of consciousness, which does not occur in vertigo. When fits of vertigo are likely to pass into epilepsy, a momentary loss of recollection or consciousness then generally characterizes them. The difficulty in the diagnosis respects chiefly the pathological condition of which vertigo is a chief or related manifestation—as regards the states of organic nervous or vital power, and of vascular action or congestion in the brain—as to the affection being a precursor of a febrile or exanthematous disease, or a symptom of disordered digestive function, or of misplaced gout, or of most serious disease, or of structural lesion of the nervous masses within the cranium. This, the most important diagnosis of vertigo, entirely depends upon the peculiarities of individual cases; upon the age and previous diseases of the patient; upon the recognised and presumed causes of the affection; upon the states of organic, nervous, or constitutional power, and of local and general vascular action; and upon the phenomena observed, and the symptoms ascertained, during the disorder. It must be apparent from this that the knowledge, acumen, and experience of the physician will be called into requisition in most cases of vertigo; and his success in their treatment will altogether depend upon the pathological inferences he may form.

10. There are other circumstances than the above to which attention should be directed; and among these the probable existing morbid states causing this affection at different periods of life may be noticed. If the disorder occurs soon after, or even several years after, puberty—and if the patient be thin, pallid, or anæmic, and be incapable of directing his eyes firmly on the person addressing him, impaired nervous power, very probably occasioned by masturbation, may be inferred. If the affection occur in mature or advanced age, although it may proceed from disorder of the digestive organs, it may, as well as such disorder, be much more likely a prominent symptom of disordered circulation in the brain, caused either by atheromatous, fatty, ossific, or other changes in the coats of the arteries, or by disease of the heart, of its valves, or even by organic lesion of the intimate structure, or by more mani-

fest alterations of the brain, either consequent upon one or other of these morbid conditions of the vessels, or taking place independently of them. I have seen cases where this affection has been produced by these several lesions, by scrofulous, tubercular, cancerous, or other formations in the membranes or substance of the brain, and by impeded return of blood from the head. In a remarkable case of colloid cancer of the mamma, under my care a few years ago, that was seen by Dr. RAMSBOTHAM and Mr. FERGUSSON, the cancerous disease ultimately invaded the brain, occasioning, for a considerable period, constant vertigo, and ultimately general paralysis and coma. The connexion, also, of vertigo with the gouty diathesis, and the occurrence of it as a form of misplaced gout, should not be overlooked when it affects persons of mature or advanced age, especially when the exact nature of this affection is clinically investigated. The connexion of this affection, also, with cachectic states of the system, with imperfect excretion and depuration of the blood, and with disordered function or organic lesions of the kidneys, but still more intimately with organic lesions of the heart, its orifices, or of its valves, demands due consideration. Several instances of chronic vertigo have come before me which had been referred to cerebral disease, but which, upon auscultation of the heart, were found to depend upon impeded return of blood from the head, owing to interrupted circulation through the heart.

11. II. THE PROGNOSIS of vertigo should be always given with caution, and often with much reservation. In some cases, especially in early or middle age, when the affection is slight, and depends chiefly on disorder of the digestive organs, or the organic nervous system, a favourable opinion may generally be given, unless there be reasons to infer that it is a precursor of fever of an exanthematous or any other form; and then the result will entirely depend upon the consecutive disease. Whenever the affection occurs suddenly or in fits, then its passage into fully-developed epilepsy should be dreaded, however judicious the treatment may be, more especially if there be any reason to infer that it is caused by masturbation, or by excessive venereal indulgences. Of this causation and transition of vertigo, many cases have come under my observation, not only in early and middle, but also in far-advanced age. In this last period of life, as well as in middle and mature age, vertigo, in any of its grades, should always be dreaded and viewed as a precursor of a more serious or dangerous attack. In these cases the symptoms connected with the organs contained within the cranium should be carefully observed, especially the several senses; the temperature of the scalp, the state of the pulse in the carotids; the action, rhythm, and sounds of the heart, and the appearance of the veins of the head and neck, and an opinion be given conformably with the evidence furnished by these sources, the juvenia and lædientia being also taken into due consideration.

12. III. THE TREATMENT should be based upon the inferences arrived at as to the causes and pathological states of vertigo.—(a) If the causes inferred be such as reduce organic, nervous, or constitutional power, and if they are of such a nature as are likely to convert the disorder into either hysterical or epileptical seizures, as certain of the causes above noticed (§ 6, *et seq.*), a restor-

ative, antispasmodic, or tonic treatment, such as the preparation of valerian, asafœtida, zinc, &c., cod-liver oil, oxyde of silver, &c., ought to be prescribed; and if there be any indications at the same time of local or general anæmia, chalybeates, either alone or in addition to these means, are also required. In cases of this description, as well as in those indicating a tendency to assume either an hysterical or epileptic character, I have found the tincture of sunbul, either alone or conjoined with other medicines of a tonic or antispasmodic nature, of great service in several cases. In these, also, I have prescribed the cotyledon umbilicus, but not with so marked benefit as I expected, although it also was sometimes very beneficial.

13. (b) In persons who are liable to vertigo from prolonged or profound thought and reflection (§ 5), and especially if the scalp be hot, and vascular determination to the brain, as evinced by the action of the carotids, be excessive, cooling applications to the brain, local depletions, internal and external derivations, purgatives, a regulated diet, and, above all, the avoidance of the cause, change of air, of scene, and of habits, travelling, voyaging, &c., and relaxing amusements, or agreeable and slight occupations merely, are the means upon which the chief reliance should be placed.

14. (c) In persons of a full habit of body, in those who live luxuriously, or even moderately, and who take little exercise, the temperature of the scalp, the pulsation of the carotids, or the action or sound of the heart, indicating local or general plethora, or impeded return of blood from the head, the occurrence of vertigo should be viewed in a very serious manner, and local depletions, derivations, both external and internal, purgatives, setons, or issues, spare diet, and regular exercise in the open air, are generally beneficial. Other means in addition to these may be resorted to; but they must be left to the judgment of the physician, who will prescribe them appropriately to the features characterizing individual cases. Emetics, the application of cold to the head, the restoration of suppressed hæmorrhages, bleeding from the nostrils, and venæsection, were the chief means recommended by ARETÆUS for vertigo, and they are indicated in the circumstances just now mentioned; but emetics should follow, not precede, the other means when cerebral or general vascular plethora is present.

15. (d) In cachectic habits of body, in cases manifestly depending upon disorder of the digestive organs, and when the temperature of the scalp, and the local and general states of the circulation and of vascular action, present no contradiction of the propriety of the practice, the treatment of vertigo may be initiated by the exhibition of an emetic. When this affection is indicative of the commencement of fever, or of one of the exanthemata, and is attended by lassitude, pains in the back or limbs, or by chills or shivering, this practice is then also productive of benefit; but ipecacuanha or sulphate of zinc should be preferred to antimony as an emetic; or, if this last be prescribed, it will be advantageously conjoined with a warm, aromatic, or antispasmodic medicine, such as Cayenne, ginger, &c.; but it ought not to be repeated oftener than once. Vertigo in the gouty diathesis requires, in the first instance, chologogue purgatives, followed by alkalies, magnesia, sulphur, and other vascular depurants, which increase the functions of the kidneys, skin, and digestive mucous surface. In

all cases of vertigo unconnected with the invasion of either of the forms of fever, the previous habits, modes of living, and disorders of the patient should be ascertained, and a more or less complete change of these habits be insisted upon, as far as his age and other circumstances may render the change advisable.

#### VOICE AND SPEECH—DISORDERS OF.—1.

Voice and speech are functions by means of which the human species claims and maintains an ascendancy over all animated nature. The more perfect animals, including the winged creation, possess the power of emitting vocal sounds, which admit of such changes in power, modulation, and character as convey intimations to individuals of their own genus or species of danger, of pleasure, of sources of nourishment, of desire, and even of affection. The practised ear can recognise, in nearly all animals which emit sounds, variations in cadence, character, and power, which are known by the same species as announcements of the presence of objects of prey and subsistence, of sources of danger, of the loss of offspring or objects of affection, and of danger, suffering, or distress. And it is by no means improbable that

the sounds characteristic of individual species, even of the lowest capable of emitting them, are so modulated as to convey to one another the various instincts and suggestions which seasons, localities, and external circumstances and influences may excite; the sounds thus modulated becoming known, as regards each species, as a distinct, but limited language, although unknown, unless in its more manifest and prominent characters, to man.

2. The sounds produced by the organs, so wonderfully and beautifully provided for them, in the human species, are the chief means of developing the mental faculties, of exercising dominion over the rest of the animal creation, and of acquiring and of exerting power over those requiring guidance or governance. The sounds produced by the human organs of vocalization and articulation are the manifestations furnished to the species of the finest sentiments, of the deepest as well as the highest states of feeling, of the most profound and abstract results of thought, and the wisest and best revelations of mental reflection and of human reason. But considered philosophically, they are studies rather for the physiologist than for the pathologist. To the latter, however, the more strictly philosophical consideration of human sounds, as manifested in the modulated voice and in speech, becomes a necessary introduction to an intimate knowledge of the several modes in which both voice and speech are disordered, or more or less impeded, or even lost. For these preliminary sources of knowledge the reader is referred to the recent writings of MÜLLER, CARPENTER, TODD, BOWMANN, BISHOP, and WILLIS, which are in the hands of most medical men.

3. Vocal sounds and articulate speech or language are two distinct functions; and although the latter proceeds from the former, an additional apparatus is required for its production. The instrument of vocal sound, the larynx, is distinct and appropriate to this purpose, and is calculated by its mechanism to produce the several grades and modulations of voice; but, although thus independent, the vocal sounds cannot be modified into articulate speech, or even into a near approach to articulation, without the aid of the *oral cavity*, more especially of the *tongue*. Hence there may be vocal sound without speech; but this latter cannot be produced without the former; and hence both may be separately or even conjointly disordered, or even lost. But, although speech may be altogether lost, a vocal sound can hardly be quite lost while respiration is performed, unless in complete syncope, catalepsy, apoplexy, in the coma of fever, and in other occasions of loss of sensibility and consciousness; for even in these states, unless in profound syncope and catalepsy, a simple or low respiratory sound may still be emitted.

4. I. Voice is produced, according to Mr. BISHOP, by the conformation of the vocal apparatus, which combines the properties of a stretched chord, a membranous pipe with a column of air vibrating in it, and a reed, and is the perfect type, of which these instruments are only imperfect adaptations. Dr. CARPENTER states "that the sound is the result of the vibrations of the vocal ligaments, which take place according to the same laws with those of metallic or other elastic tongues; and that the pitch of the notes is chiefly governed by the tension of these laminae." However the various tones, modulations, &c., of the

voice may be explained, or referred severally to the especial or combined movements and actions of the different parts constituting the vocal apparatus by physiological writers, it must be manifest that a healthy condition of the vocal chords and ligaments, of the cartilages, of the muscles which move them, and of all the parts both above and below the larynx, as well as of the larynx itself, and the mucous membrane covering it and its vicinity, and even of the velum palati also, is necessary to the production of the human voice in its natural and perfect state; and consequently that this function, capable of the utmost perfection, of the greatest range in power and modulation, and of astonishing improvement as regards these, by careful and scientific cultivation, depends upon a perfect condition of their several parts, disorder or structural lesion of any one of them affecting the voice in a more or less remarkable manner.

I. APHONIA.—LOSS OF VOICE.—SYN.—*Ἀφωνία* (from *a priv.* and *φωνή*, voice). *Aphonia*, Vogel, Sagar, Cullen. *Dysphonia*, Good. *Raucedo paralytica*, Darwin. *Perte de la Voix*, Fr. *Die Stimmlosigkeit*, *Aphonie*, Germ.

CLASSIF.—IV. CLASS, II. ORDER. (See Preface.)

5. DEFINIT.—*More or less impairment or complete loss of the power of emitting vocal sound, owing either to functional disorder or to structural lesion.*

6. The voice may be impaired in every degree from the slightest catarrhal form to the most complete loss from organic change. The impairment or loss may be either temporary or permanent. The slightest as well as the less permanent aphonia often proceeds from functional disorder, especially from extreme nervousness, fright, fear, and hysteria; but it also is frequently caused by catarrhal congestion of the mucous membrane of the larynx and of the subjacent cellular tissue, and by temporary impediment to the movements of the vocal chords from this cause, or from inflammation and its results implicating for a time any of the parts of the vocal apparatus. In the more strictly nervous states of aphonia there is no manifest lesion of structure, the nerves supplying the laryngeal muscles and chords having become for a time incapable of conveying the dictates of volition to these parts, unless volition be most energetically exerted.

7. A. FUNCTIONAL APHONIA occurs chiefly in delicate, nervous, or hysterical females, and much more rarely in similarly constituted males. In the former sex it is most frequent about and subsequent to the period of puberty, and during the catamenial epoch of life; in the latter chiefly before the period of puberty, and only in very rare cases, and when occasioned by fear or fright, and it is then of short duration only.

8. *Hysterical aphonia* may be viewed as one of the forms of functional paralysis, which not unfrequently complicates disorder of the female organs, such disorder being generally either not otherwise manifested, or latent, or masked by some other affection. In most cases it is easy to distinguish the hysterical from all other forms of aphonia; other allied symptoms, the previous history of the case, the state of the uterine functions, the moral affections, impressions, and sentiments, which may have preceded the loss, &c., generally indicating its nature. It should not be overlooked that, in hysterical females, more especially in those most subject to uterine or sexual

irritation, aphonia is sometimes *feigned*. In rare instances, also, it may be difficult to determine whether or no it is hysterical or owing to structural disease in or near to the base of the brain; and this difficulty is increased, 1st, by the absence of other hysterical symptoms; and, 2d, by the presence of other states of cerebral paralysis, the catamenial functions or organs having been previously disordered. I was recently called in consultation to a delicate, nervous female, aged 18, who had menstruated irregularly and scantily, and was seized with incomplete hemiplegia and complete loss of voice—the muscles of the face not being affected. In this case it was difficult, at first, to determine whether the aphonia was hysterical or owing to some lesion within the cranium, causing also the hemiplegic affection. Then history and progress, however, generally elucidate the nature of these cases.

9. *B. STRUCTURAL APHONIA* is caused, *firstly*, by changes implicating one or more of the parts composing, or in the immediate vicinity of, the vocal apparatus; and, *secondly*, by lesions at the origin or in the course of the nerves distributed to the laryngeal muscles and vocal chords. The slighter or more incomplete forms of aphonia are those of a catarrhal nature, arising from more or less congestion and tumefaction of the mucous and sub-mucous tissues of the larynx and adjoining parts. Severe cases of aphonia are often occasioned by serous infiltration into the sub-mucous tissue, with or without inflammation of the mucous membrane of the larynx and of its vicinity, in the direction either of the fauces or of the trachea, or of both. This serous infiltration may be slight, and continue only during the catarrhal attack, or it may be so very considerable as to nearly suppress the voice altogether and cause suffocation, as observed in *œdema* of the glottis and epiglottis. Aphonia from this and other affections of the vocal apparatus is fully considered in the articles LARYNX and TRACHEA, where the lesions which affect the voice are described, and the treatment appropriate to each pointed out. The voice may also be affected in different degrees by inflammatory affections of the fauces, pharynx, and tonsils, by tumours in these situations, or by morbid growths pressing upon or implicating the larynx or trachea, by aneurisms, and most frequently by chronic laryngitis and its consequences, especially thickening, ulceration, &c., arising either primarily or consecutively of acute laryngitis, or of tubercular disease of the lungs, or of syphilitic infection. All these are fully discussed in the articles now referred to; but in all the voice is affected rather than the power of articulation, which is perfect as far as the production of vocal sound admits; for the affections of the larynx in such cases are rarely associated with any interruption to the movements of the tongue and of the parietes of the oral cavity, by means of which articulation or speech is performed.

10. II. DEFECTUS LOQUELÆ.—SYN.—*Alalia*, Frank. *Loquela Abolita*, Auet. Var. *Mutitas*, Sauvages, Macbride, &c. *Sprachlosigkeit*, *Stummheit*, Germ. *Loss of Speech*.

11. *Voice*, as stated above, is produced by the larynx, its modulations into musical sounds being effected by means of this organ aided by the epiglottis and adjoining parts. *Speech* is the modification of the voice, or sounds emitted by the larynx, by the organs or parts intervening between

it and the os externum. It is obvious that, to produce articulate sounds, forming language, the movements of the tongue, fauces, and connected parts must be complete; and that these should be in a healthy condition to render articulation perfect. The tones of the voice, and articulate speech, cannot be produced in childhood, when the sense of hearing is completely lost in early infancy, or in the fetal state; and as long as the sense of hearing continues lost, *dumbness* is the result: for the sense required to *dumbify* and adjust vocal sounds does not exist.\* *Voice*, especially in its healthy and cultivated states, and in its modulations into music, is capable of expressing the several emotions of mind, in a more remarkable degree and manner than articulate speech; but *speech* or language has a much greater, more varied, and more extensive power of addressing, informing, and enriching the intellect, of furnishing definite ideas of objects, properties, actions, &c., and of conveying the results of reflection and of rational deductions. The vocal organ, aided by the movements of the tongue and parts composing the oral cavity, is adapted for, and in health is capable of, forming a number of simple sounds, which are readily combined into groups forming words. Dr. CARPENTER justly remarks, that the number of combinations which can be thus produced is so inexhaustible that every language has its own peculiar series, no difficulty being found in forming new ones to express new ideas. There is much diversity in different languages, even with regard to the use of the simplest of these combinations; some of them are more easy of formation than others, and these accordingly enter into the composition of all languages; while, of the more difficult ones, some are employed in one language, some in another; no one language possessing them all, or using them to any co-ordinate extent.

12. The mechanism producing vocal sounds being complicated, and actuated in its individual parts and in its combined movements by volition, and by the states of vital force, as influenced by health, constitution, and disease, and adjusted by the sense of hearing, it necessarily follows that the faculty of speech, in whatever language, will be modified, altered, interrupted, impeded, and even altogether lost, in numerous modes, so as not only to furnish most important indications of disease of the slightest as well as of the most dangerous nature. The articulate sounds which have become familiar to the ear are often remembered as long as the appearance of the person by whom they were furnished; and the per-

\* The finest modifications and adjustments of the actions of the muscles of the larynx, and of the several parts of the fauces and oral cavity, are requisite to the production of determinate tones, accents, and speech; and these actions are ordinarily adjusted and modified by the sense of hearing. Hence a fine or educated ear in music is of great advantage in singing and in the pronunciation of languages. This adjustment, being learned in the first instance under the guidance of the sounds actually produced and heard, is subsequently effected voluntarily, in accordance with the mental conception—or inward sensation—of the tone or sound uttered, which conception cannot be formed unless the sense of hearing has previously brought similar tones to the mind. Hence it is that persons who are born, or become, quite deaf before articulate speech is formed or attempted, are also *dumb*. They have no malformation, no paralysis of any part of the organs of voice and speech; but they cannot utter distinct musical tones or articulate speech, because they have not the guiding conception or sensation of the nature and character of these sounds, furnished by the sense of hearing.

son, even after many years, is often recognised by his voice and speech before he is seen. Debility weakens the articulating power, or the strength of articulate sound; but disease may alter it more remarkably, different maladies affecting it in various ways. When the voice is altered, or lost by disease, the speech is then necessarily similarly circumstanced, as already stated (§ 5, *et seq.*). But speech is more especially affected as a precursor, or as a symptom, of apoplexy and paralysis; and, when so affected, it indicates the most serious results at a period which, although indefinite, may generally be viewed as comparatively short. In cases where speech is altogether lost, especially at an advanced age, or is so nearly lost as hardly to be understood, or when the sounds are mostly inarticulate, if no apoplectic or paralytic seizure have preceded or accompanied this loss, then either of these seizures may be expected before a long time elapse, unless the time be deferred by treatment, and diet, and regimen; and more frequently, notwithstanding these means of prevention. (See *arts.* APOPLEXY and PARALYSIS.)

13. *Loss of speech*, whether complete or incomplete, is generally to be imputed to structural disease, wounds, or fractures, implicating either parts within the cranium, or the nerves in their course to the organs of articulation. Cases of loss of speech, consequent upon apoplexy, or associated with other paralytic states, are very frequent, and are by no means rare as a precursor of a dangerous apoplectic or paralytic attack. When thus present, as the only apparent ailment, the result is not the less to be dreaded. In several cases, for which I have been consulted in the course of my practice, speech was so completely lost, that no articulate sound was produced, the simple vowel-sounds *a* and *o* being only emitted, and yet none of the organic, or of the cerebro-spinal functions, and none of the senses, evinced any disorder. In all these, an apoplectic, hemiplegic, or more general paralytic seizure supervened generally in a few weeks or months, owing to the development of latent pre-existing organic lesion. Whenever, therefore, the faculty of speech becomes impaired, or is lost by persons who had previously possessed this faculty in a healthy state, more especially if this change occur in mature, middle, or advanced age, it should be viewed as a form of local or partial paralysis, which is generally followed, at no very remote period, by a very dangerous form of apoplectic, or of more general paralytic seizure.

14. III. IMPEDIMENTS OF SPEECH—HESITATIONS OF SPEECH—STAMMERING—STUTTERING.—This affection is generally functional, or of a nervous nature, and may present several forms. These are usually observed in childhood and in early life; while incomplete or complete *loss of speech*, briefly considered above (§ 13, *et seq.*), is the consequence of structural lesion or of injury, and is a form of paralysis of a most dangerous nature. Hesitations in articulating sounds, or a momentary impediment in uttering certain words or letters, or a stammering, or repetition of certain consonants, are generally observed from infancy or childhood, but they may increase or diminish, or even disappear as age advances. They may continue during a long life, or they may occur only occasionally. In this latter case they are induced or aggravated by fear, anxiety, and various mental emotions. They cannot be mis-

taken for impairment or loss of the previously healthy power of articulation, which, as stated above (§ 13), proceeds from slowly-formed organic lesions implicating the origins or course of the glosso-pharyngeal nerves; and which occurs under different circumstances, and is attended and followed by very different phenomena and consequences.

15. The muscles employed in the production of definite vocal sounds and of articulate speech, being actuated by volition conveyed from the brain to these muscles by means of the nerves proceeding from the former to the latter, it necessarily follows that both voice and speech depend on the capability of the brain to generate or exert volition, and of the nerves to convey this act to the muscles. Thus speech, as well as voice, requires for its perfection a due exertion, and a healthy transmission of volition, by means of the nerves, to the apparatus destined for its production; and, if volition be feebly exerted, or imperfectly transmitted to the muscles concerned in articulation, various imperfections of these functions will result. But the complete performance of both voice and speech depends also upon the healthy functions of the lungs and respiratory passages, these functions being modulations of expiration by means of the larynx, tongue, fauces, oral cavity, and lips.

16. Thus it is apparent, as remarked by Mr. BISHOP, that "the mechanism provided for the production of speech comprehends a large assemblage of organs. The most simple vocal sounds require the combined action of the lungs, windpipe, larynx, and respiratory muscles; and for articulate language, an additional set of organs must be called into play, namely, the pharynx, hard and soft palates, uvula, tongue, teeth, lips, and nostrils."

17. It is justly observed by Dr. CARPENTER that, "great as is the number of muscles employed in the production of definite vocal sounds, the number is much greater for those of articulate language; and the varieties of combination which we are continually forming unconsciously to ourselves, would not be suspected, without a minute analysis of the separate actions. Thus, when we utter the explosive sounds (explosive consonants), we check the passage of air through the posterior nares, in the very act of articulating the letter; and yet this important movement commonly passes unobserved. We must regard the power of forming the several articulate sounds and their simple combination, as so far resulting from intuition, that it can in general be more readily acquired by early practice than other actions of the same complexity; but we find that, among different races of men, there exist tendencies to the production of different sounds, which, though doubtless influenced in great degree by early habit (since we find that children, when first learning to speak, form their habits of vocalization in great degree in accordance with the examples amid which they are placed), are certainly also dependent in part upon congenital constitution, as we often see in the case of children among ourselves, who grow up with certain peculiarities of pronunciation, not thus derived from imitation, of which they do not seem able to divest themselves."

18. I must refer the reader to Mr. BISHOP for a notice of mechanical contrivances for the production of vocal sounds; but these can never suf-

ficiently illustrate the intonations of voice or the production of articulate speech, or even satisfactorily show what it is that constitutes the essential character or distinction between the vowels, and on what part of the mechanism of the voice the vowel-sounds depend. These sounds, as well as those of the consonants, are formed by so slight changes in the relative position of the several parts of the complex organs of voice and speech, varying in accent and intonation so remarkably with the language, &c., as hardly to admit of any estimate. Mr. BISHOP observes that, "in the application of the theory of vowel-sounds to the mechanism of the human voice and speech, there are two hypotheses which would equally satisfy the conditions for their production artificially. The first is, that the glottis produces the primary, and the *air* in the pharynx, mouth, and nostrils, the secondary or vowel quality pulsations. The second is, that the glottis produces the primary, and the *membranes* of the pharynx, mouth, and nostrils produce the secondary pulsations of the air." Dr. THOMAS YOUNG observes, in respect of the first of these, that the "reflection of the sound from the various parts of the cavity of the mouth and nostrils, *mixing* at various intervals with the portions of vibrations directly proceeding from the larynx, must, according to the *temporary form of the parts*, variously affect the laws of the motion of the air in such vibration."

19. As to the second view, Mr. BISHOP remarks, that "we know by experience that the breath passing through the glottis is thrown into a certain state of vibration, and reaches the cavity of the mouth, which is already so disposed as to present a proper extent of its own membranes to the action of the breath. By these means the membranes are also made to vibrate, and these latter vibrations, coexisting with the original vibrations of the glottis, may generate the vocal sounds." Now the chief objections which may be offered to this view are, that the surfaces of parts, over which the vibrations of air from the glottis pass, are not membranous or are not membranes capable of vibration, but are surfaces constantly changing their configurations by means of the muscles by which they and the subjacent parts are actuated, the vibrations of air thrown out by the glottis being modified or changed by the alteration in the configuration of these surfaces—of the surfaces of those parts between the glottis and the external features—so as to produce the different vowel-sounds, and to pass from one simple vowel-sound to another. Without attempting to proceed farther in the consideration of the other simple sounds, or of the physiology of voice and speech, my limits oblige me briefly to notice the more practical part of this subject.

20. Very great ignorance, some mischief, and no little discredit to medical science, have been displayed by the energetic proceedings of some surgeons who have either written upon *stammering* and *stuttering*, or who have officiously meddled with, and injuriously operated upon, certain parts which are in no way implicated in the disorder under consideration. It has been supposed by these meddlers, with surpassing profundity, that these momentary or temporary affections arise from some lesion of the muscles of the tongue, or of the *frænum lingue*, or of the *velum palati*, or of the *uvula*, or even of the tonsils, each

acting on his own peculiar inspiration—with a success properly exposed by Mr. BISHOP, and sufficiently manifested to my own observation. It must be very demonstrative of the progress of surgical science to see one surgeon "dividing the muscles of the tongue at its root, cutting at the same time through the linguales, the *genio-hyo-glossi*, and *stylo-glossi* muscles, with their blood-vessels and nerves; or cutting a transverse wedge-shaped slice out of the dorsum of the tongue!" Or another surgeon extirpating the tonsils, which may affect the pitch and the quality of the voice, but which can have nothing to do with stammering! Or a third surgeon cutting off the *uvula*, which is unconcerned in articulation! Now these pleasant operations have all been done, and may be done again and again, under the seductive and perfectly safe (!) influence of chloroform, but what are the results! Let the victims articulate the answer, if they can intelligibly—for I have seen some of them who found this very difficult. For, as I have already noticed in another place, both the *uvula* and the tonsils perform functions necessary to the perfection of both voice and speech; and if these be removed, the pharynx and glottis are insufficiently lubricated, and are liable to experience, in consequence, more or less irritation, often passing into chronic inflammatory action, as have been demonstrated by cases which have come under my observation, and in which these parts had been extirpated. In other cases, where these effects have not appeared, or where the speech has been without huskiness, or any lesion of distinct articulation, the voice has been so much injured as to prevent attempts to sing.

21. There are several *conditions* which combine to produce stammering, each being more or less concerned in the morbid effect. The *first* is imperfect vocalization, or an insufficient expiration, owing generally to an imperfect respiration or to the lungs having been nearly emptied of their due quantity of air at the moment of articulation; the *second* is an insufficient force of volition, by which the act of articulation is attempted; the *third* is, generally owing to the foregoing, a want of synchronous and appropriate action of one or more of the parts concerned in the production of voice and speech; and *fourth*, an irregular or spasmodic action of some of the muscles engaged in articulation. This last state is generally, also, a consequence of attempts at articulation being made either without sufficient force of volition, or without due vocalization, or during an insufficient expiration from defect of air. It follows from the above that the chief source of stammering is to be referred to the nervous centres—more especially to the seats of volition and emotion, and to the functional condition of the *medulla oblongata*.

22. Dr. CARPENTER has justly remarked the analogy between stammering and chorea, the former being sometimes one of the modes in which the disordered condition of the nervous system in chorea manifests itself. "The slightest disturbance of the feelings is sufficient in most stammerers to induce a complete perturbation of the vocal powers; the very fear that stammering will occur, particularly under circumstances which render it peculiarly annoying, is often sufficient to bring it on in a predisposed subject; and the tendency to consensual imitation sometimes occasions stammering in individ-

uals (especially children) who never show the slightest tendency to it except when they witness the difficulty in others."

23. That one or more of the *four conditions* which I have stated to be chiefly concerned in the production of stammering actually exists, will appear from what is observed as to the manner in which timidity, fear, and anxiety affect these conditions, and, by thus affecting them, produce in many persons either stammering or stuttering; although they are not subject to these disorders of articulation in other circumstances. On this topic Mr. BISHOP very correctly remarks: "The emotions which arise in a person when he is about to address an audience are often so overpowering that the voice loses its natural volume, becomes tremulous, and sometimes inaudible, the respiratory functions are irregular, the flow of ideas is impeded, and the articulating organs perform their office so imperfectly, that he who is generally ready and fluent in conversation hesitates, stammers, and cannot utter a single connected sentence. Now if persons, who at other times have a perfect voluntary control over the organs of voice and speech, partially lose it under the circumstances just mentioned, *à fortiori* those who have at all times an imperfect control over their articulation will, in similar states of feeling, find their powers paralyzed, and their speech more than usually defective."

24. But it is chiefly in childhood and boyhood, when the sensibility and the emotional susceptibility are greatest—while the due co-ordination of those movements of the parts which contribute to correct articulation is either being formed, or is in the course of development, or only recently perfected—that stammering either commences or is chiefly manifested. At these ages, and more especially in those children in whom the faculty of speech is slowly developed, or appears only at a later period than usual, the emotions are most likely to disturb the force of volition, and, with this disturbance, the normal exercise of the intellectual, the respiratory, the vocal, and the articulating functions.

25. Whatever may be the cause or nature of the changes in the brain corresponding to the several emotions, they are propagated to the medulla oblongata, and influence the action of the respiratory and the motor nerves of the face, throat, and tongue, as well as other nerves, and through them the muscles they supply. The emotions may thus occasion irregular actions of the parts concerned in articulation: 1st, by causing a momentary spasm or closure of the glottis, and thereby arresting all vocal sound; 2d, by causing irregular action, or by closing the isthmus of the fauces and obstructing the pronunciation of letters and syllables which begin with *guttural letters*; 3d, by the irregular or spasmodic motion of the tongue, the dorsum of this organ being carried backward, or brought into contact with the palate, thereby affecting the *lingua-dentals*, *lingua-palatals*, and *lingua-palatonasals*, and syllables or words commencing with these letters; and, 4th, by closing the lips and posterior nares, by affecting the pronunciation of the *labials*, and even also of all the other letters. An acute and experienced observer may readily detect the particular cause of obstruction—whether the glottis, fauces, the dorsum or tip of the tongue, or lips.

26. IV. THE TREATMENT of stammering must

be based upon the result of observation as to the seat of difficulty, or obstruction in the organs of articulation. Dr. ARNOTT proposes that all the words should be connected by a vocal intonation, in such a manner that there shall never be an entire stoppage of the breath. But the difficulty is often at the commencement of a word or sentence, especially when the glottis is spasmodically or irregularly affected; and, as MÜLLER contends, this plan cannot do all that is required, as the impediment often occurs in the middle of words, although it may afford some benefit. The most important remedial means is that much insisted upon by Dr. CARPENTER, and this is to study carefully the mechanism of the articulation of the difficult letters, and to practice their pronunciation repeatedly, slowly, and analytically. "The patient would at first do well to practice sentences from which the explosive consonants are omitted; his chief difficulty, arising from the spasmodic suspension of the expiratory movement, being thus avoided. Having mastered these, he may pass on to others, in which the difficult letters are sparingly introduced; and may finally accustom himself to the use of ordinary language. One of the chief points to be aimed at is to make the patient feel that he *has* command over his muscles of articulation; and this is best done by gradually leading him from what he finds he *can* do, to that which he fears he *cannot*." (*Op. cit.*, p. 771.)

27. The circumstance of stammerers being often able to *sing* their words better than to speak them has been explained by the supposition that, in singing, the glottis is kept open, so that there is less liability to its spasmodic action; but, in singing, the velum palati, and the other parts concerned in articulation, are also much less liable to irregular or spasmodic action, they being brought less into action than in articulation. The difference may, however, as Dr. CARPENTER supposes, be due to the direction of the attention rather to the muscles of the larynx than to those of the mouth. One of the most obvious and important objects in the treatment of stammering is the prevention of any emotional disturbance during the act of speech; "and this requires the exercise of the voluntary powers over the direction of the thoughts, in the following modes: 1st. To *reduce* mental emotion, by a daily, hourly habit of abstracting the mind from the subject of stammering, both while speaking and at other times; 2d. To *avoid exciting* mental emotion by attempting unnecessarily to read or speak, when the individual is conscious that he shall not be able to perform these actions without great distress; 3d. To *clude* mental emotion, by taking advantage of any little artifice to escape from stammering, so long as the artifice continues to be a successful one." Having mastered the articulation of the difficult letters, and of the words containing them, and having thus avoided or overcome mental emotion, the patient should practice reading and speaking aloud, slowly, and with due enunciation and intonation, and with a full and free respiration, never allowing the lungs to become too far exhausted of air. Due attention should also be paid to the digestive and excreting functions, and to the improvement of the organic nervous force and of the mental powers, by air, exercise, medical treatment, and diet. Frequent declamation, and reading or reciting aloud such passages as interest the mental emo-

tions, should be practiced as soon as the patient has acquired a complete command over his articulation and over the difficulties which mental emotions have occasioned him.

[Did our limits permit, it would be interesting to trace the history of the treatment of stammering, in this country, from the empirical modes adopted by teachers down to the still more empirical practice of various surgeons, who, following in the footsteps of DIEFFENBACH, severed the muscles at the root of the tongue, removed a V-shaped portion from its substance, or excised the tonsils and uvula, mistaking the temporary relief produced by the strong mental impression caused by the operation for a permanent cure; and this, too, when it is well known that a severe toothache, rheumatic affections of the jaws or face, tic-doloureux, ulcers on the tongue or inside of the lips, and other casualties, will cause a temporary cessation of stammering. The late Dr. C. C. YATES, of New York, was the first to hit upon a philosophical and successful method of treatment. This was imparted to the governess in his family, Mrs. LEIGH, who, in connexion with him, established an institution for the treatment of such cases, which was carried on for many years with very remarkable success. Pupils flocked to them from every part of the Union, and were in most cases speedily cured. Other teachers, instructed by them, established other schools in different parts of the United States, and were equally successful in effecting speedy cures. The result which followed was what might have been anticipated; the cures obtained were so numerous and wonderful, and attended with so much profit to the teachers, that multitudes of other persons soon set up to cure impediments of speech who were totally unqualified, and the system soon fell into disrepute. At present very little is heard of the system, and it would seem to have been generally abandoned. Dr. YATES's method may be found fully and very ably described by Dr. E. WARREN, of Boston, in vol. xxi. of the *Am. Jour. Med. Sciences*, p. 75. One thing is certain, that, although apparent cures are easily made by this system, and appear perfect for the time, there is great danger of a relapse unless confirmed by long habit. In a few cases they will remain permanent, but in a majority, unless the course is persisted in, the difficulty returns. Whatever method is employed for the relief of this affection, in a majority of cases no permanent advantage will be gained unless resolutely persevered in for one or two years.]

CLASSIF.—PATHOLOGY—SYMPTOMATOLOGY AND THERAPEUTICS.\* (See Preface.)

\* The mechanism of vomiting has been a subject of discussion with both physiologists and pathologists. Three principal opinions have been entertained on this subject. MAGENDIE was of opinion that the stomach was passive in the act, and that the contraction of the diaphragm and abdominal muscles on that organ is the sole cause of the phenomenon. "This view was adopted by RICHERAND, ROSTAN, and PIEDAGNEL; while MARQUAIS, MAINGAULT, PORTAL, TANTINI, GRAVES, STOKES, and HALL have embraced more or less contrary opinions." MAINGAULT attributed vomiting exclusively to a gradual anti-peristaltic movement and contraction of the stomach. PORTAL concluded that this act takes place during expiration, consequently during relaxation of the diaphragm. That vomiting may take place without the action of the diaphragm is shown by a case observed by Drs. STOKES and GRAVES, where vomiting was a principal symptom, but the stomach was found situated above the diaphragm. In a case recorded by M. LEPSIE (*Bullet. de l'Acad. Roy. de Med.*, 1844), in which the abdominal parietes having been accidentally laid open in the human subject, and the stomach having wholly protruded itself, it was seen to contract itself forcibly and repeatedly, until, by its own efforts, it had expelled all its contents except gases. The relaxation of the cardiac sphincter is essential to the act of vomiting, for its fibres can resist, by their contraction, the combined force of the expulsive muscles. The retchings or fruitless efforts at vomiting are owing to the contrac-

1. DEFINIT.—The rejection of the contents of the stomach, with or without retchings, generally symptomatic of visceral or of constitutional diseases, but sometimes occurring independently of these, or of any serious derangement: RETCHING is an ineffectual effort to reject the contents of the stomach, or painful contractile efforts, either before the stomach is evacuated, or afterward, and when the stomach is empty.

2. Vomitings and retchings are subjects of great interest: 1st, as symptoms of disease; 2d, as a therapeutical indication; and, 3d, as a prominent manifestation, if not a primary or idiopathic state, of serious disorder. The first of these is considered in the article on SYMPTOMATOLOGY (§ 130, *et seq.*), as well as in the history of the several forms of disease; the second is partially noticed under the head of THERAPEUTICS (§ 40, 43, and 56), and in the eighth class, and the third order of THERAPEUTICAL AGENTS. Before, therefore, I proceed briefly to consider vomiting as a chief and prominent affection, requiring to be palliated or allayed, I shall notice the circumstances which appear mainly to require the artificial production of vomiting.

3. 1. VOMITING AS A THERAPEUTICAL INDICATION AND AGENT has not, in the article just now referred to, owing to the scope and object of that article, been considered so fully as its importance demands. It is more especially required when poisonous or injurious substances have been taken into the stomach; or when the stomach is overloaded by food or drink to a hurtful amount, more particularly when either or both threaten to occasion apoplexy, or any other seizure, or when these attacks actually result from these causes. In all such cases the selection of the emetic should be suitable to the cause and nature of the evil produced, and always be so energetic as to produce a rapid and full effect.

tions of the cardiac sphincter. Vomiting, like other efforts at expulsion of the contents of the natural cavities, is performed by the muscles of expiration, and while the diaphragm is relaxed and pressed up upon the lungs by the action of the abdominal muscles.

The immediate causes, or the physiological pathology of vomiting, may be stated under the following heads: 1st. The contact of irritating, poisonous, or unwholesome substances irritate the ganglial nerves supplying the villous coat of the stomach, and affect the coeliac ganglion and adjoining plexus. The morbid impression or irritation is conveyed to the roots of the spinal nerves and cord by the ramifications of the ganglial nerves to these parts, and is reflected thence, by the motor nerves of expiration, to the abdominal muscles, by what I termed a "reflex sympathy," and Dr. MARSHALL HALL long subsequently designated a "reflex function." 2d. Irritations, &c., affecting other parts of the body (as stated § 18, *et seq.*), are propagated by the splanchnic ganglia and plexuses to the stomach, and through them to the spinal cord, and are reflected in a similar manner, by the motor nerves chiefly of expiration, to the abdominal and expiratory muscles. The vomiting which thus occurs I have denominated from reflex sympathy, because it is only occasional or contingent, and not so constant or necessary an effect as to warrant the appellation of a function. 3d. Impressions made on the senses, or violent emotions, may, through the medium of the pneumo-gastric nerves, affect the ganglial centres, and either through these latter affect also, in the way above stated, the spinal cord and motor nerves, &c., or be more directly propagated to both the splanchnic and spinal nerves. 4th. Sea-sickness and vomiting cannot be referred to either of the above categories. They proceed from an impression of an irritating or depressing character—the latter more particularly—made primarily on the semilunar and other splanchnic ganglia and plexuses, and propagated on the one hand to the ganglial nerves of the stomach, and on the other to the ramifications of these nerves to the spinal nerves and cord, thereby occasioning contractions of the stomach simultaneously with contractions of the muscles supplied by the motor expiratory nerves.

4. *a.* Diseases of the *respiratory passages*, especially those attended by spasm, by suffocation, difficulty of breathing, by difficult expectoration, &c., are generally much benefited by a suitable emetic and free vomiting. Croup, whooping-cough, asthmatic seizures, spasm of the larynx, and laryngitis, congestion of the lungs, bronchitis, and bronchial catarrh, are severally relieved by emetics. In most of these, ipecacuanha, in a full dose, is the best emetic; but when there is fever or inflammatory action, the potassio-tartrate of antimony may be given, but if it fail of producing vomiting in a short time, a full dose of ipecacuanha should be exhibited. The sulphate of zinc and ipecacuanha, conjoined with capsicum or other warm spices, are most useful when vomiting is indicated during states of vital depression or exhaustion; and in cases of poisoning by sedatives, narcotics, &c.

5. *b.* The *invasion of fevers*, continued or exanthematous, is often most satisfactorily treated by an active emetic; and, as well as in affections of the respiratory passages and organs, the good effect is enhanced by the free promotion of vomiting, and by exhibiting warm diluents, especially the warm infusion of chamomile flowers, or demulcents. *Agues* and other *periodic fevers*, especially *remittent, gastric, and bilious fevers*, are also much benefited by initiating the treatment by an active emetic, and by promoting its effects by these means. Antiperiodic and febrifuge remedies, and chologogue purgatives, exert a more certain effect when they are preceded by free vomiting, artificially produced.

6. *c.* Various disorders of the *digestive canal* are most beneficially treated by procuring free vomiting at the commencement of the disorder or of the treatment. The several forms of *Cynanche* or *Angina*, especially when they embarrass respiration or deglutition, often require a recourse to emetics. In the more malignant states of *Cynanche*, or those characterizing *Scarlet fever*, the sulphate of zinc, or ipecacuanha, conjoined with capsicum or other spices, and promoted by the decoction of senega, and by tonics, stimulants, camphor, ammonia, &c., should be preferred to others.

7. *d.* Some forms of *indigestion*, or those arising from accumulations of mucous sordes, or crudities, and torpid states of the biliary formations, as indicated by a foul or loaded tongue, and by morbid appearances of the evacuations, are often the most successfully treated by commencing with an ipecacuanha emetic. All forms of *dysentery*, inflammatory or sthenic, adynamic or asthenic, acute or chronic, endemic or epidemic, simple or complicated, hepatic or scorbutic, derive benefit from free and copious vomiting, especially when produced and promoted by means suited to the peculiarities of individual cases. Ipecacuanha is, however, the emetic which is most generally applicable to dysenteric affections; and next to it the sulphate of zinc. After a free effect has been procured by means of ipecacuanha, this medicine, so valuable in *dysenteries* and *chronic diarrhæas*, may be continued subsequently, in as large doses as the stomach may tolerate, but preferably in the form of pill, combined with appropriate remedies—narcotics, aromatics, tonics, &c.

8. *e.* *Hypochondriasis* and *melancholia* are sometimes relieved for a time by an energetic emetic, judiciously selected and exhibited. But it ought, in order to be of service, to be followed by medi-

cines calculated to promote the secretions and excretions, and to impart tone and energy to the organic nervous system and to the organs which it actuates, by exercise, change of air and locality, and by travelling and occupations which both employ and interest the mind.

9. II. VOMITING AND RETCHING AS PROMINENT AFFECTIONS, OR STATES OR SYMPTOMS OF DISEASE.—Retching or vomiting may be the most remarkable and distressing symptoms, owing, 1st. To injurious or poisonous ingesta; 2d. To severe constitutional disease, as at the invasion, or in the course, of severe exanthematous or continued fevers, or of pestilential maladies; 3d. To severe functional disorder or irritation, or structural disease of the stomach itself; and, 4th. To sympathy with disease or irritation in some allied or more or less distant organ. The presence of either vomiting or retching, or of both, necessarily induces the physician to inquire, 1st. As to the exciting causes, manifest or presumed; and, 2dly. As to the pathological states to which either or both may be referred.

10. *A.* When a physician is called to a person who has previously enjoyed good health, or who has not complained in such a manner as to indicate a liability to an attack of vomiting or retching, then he should suspect the nature of the *ingesta* as having produced it, and inquire as to the food or drink, or other matters which the patient may have taken; and the matters ejected from the stomach should all be preserved for future examination, if circumstances should arise to require such examination. Where neither food nor drink is the cause, then poisonous matters taken voluntarily or accidentally, or given by others, ought to be suspected, and be carefully and artfully ascertained, and the matters rejected from the stomach carefully preserved and examined by a competent person. If poisonous substances have been taken or given, or are manifested by the character of the vomiting, by the allied symptoms, or by the state of the vomited matters, or by their presence in these matters, the antidotes and other means of treatment described with reference to the individual poisons (*see that article*) will be required.

11. *B.* When the vomitings or retchings are not caused by the ingesta, their *pathological relations* must then receive the necessary attention. In infants and children, as well also in adults, these affections may proceed from hot seasons, owing to bilious or gastric disorder; from a bilio-gastric, continued, or remittent fever; from the invasion of exanthematous fevers, especially scarlet fever and small-pox, and in the former class of patients more frequently than in the latter from disease of the brain or of its membranes. They may be the invasion of the usual forms of cholera, or of gastro-bilious disorder, during summer and autumn; or the very prominent and urgent symptoms of pestilential cholera; or, in warm climates, of hæmagastric or yellow fever. In these climates, also, they may usher in remittent or other fevers and maladies; and in all these, although most severe and even dangerous as well as the most prominent, manifestations of disease, they are very far from being the disease itself, or even the greatest part of it.

12. *C.* Severe functional disorder, local or constitutional, will occasion vomitings or retchings as that following dissipation or DRUNKENNESS (§5), and that occurring at the commencement of the

fevers, and pestilential maladies already noticed ; but the most distressing attacks of retching and vomiting are often caused by the *motions of vessels at sea*, and by *organic lesions of the stomach itself*. Of the former a more particular notice will be taken in the sequel under the head of SEA-SICKNESS, or *vomiting and retching during voyaging by sea* ; and as to the latter causes, viz., inflammation and structural changes of the STOMACH (§ 22-95), the symptoms now being considered, when arising from these lesions, are duly noticed at that place. To what I have there stated, and to the article on the pathology of the DIGESTIVE CANAL (§ 37-43), I must refer the reader. But there are other remarks which may be adduced at this place calculated farther to elucidate the history of vomiting.

13. i. VOMITING AND RETCHING FROM ORGANIC LESIONS *seated in, or implicating the Stomach*.—These lesions have been described at the places now referred to ; and, among these, *ulcerative perforation of the stomach*, either commencing in this viscus or extending to it from structural changes in adjoining parts, has occupied a conspicuous rank. These perforations may give rise, owing to previous agglutination or adhesion of the opposite serous surfaces, to communications, 1st. Between the stomach and the substance and vessels and ducts of the liver, owing most frequently to abscess in the latter viscus ; 2d. Between the stomach and the pleural cavities and lungs ; 3d. Between the stomach and pericardium ; 4th. Between the stomach and vena cava ; 5th. Between this organ and portal vein ; 6th. Between the stomach and external surface of the abdomen ; 7th. Between this viscus and the gall-bladder ; 8th. Between the stomach, gall-bladder, and duodenum ; 9th. Between the stomach and duodenum ; 10th. Between the stomach and some part of the small intestines ; 11th. Between the stomach and the colon ; 12th. Between the stomach and peritoneal cavity. Other fistulous communications between parts of the digestive canal and other viscera are met with on rare occasions, and are occasionally attended by vomiting ; but they are noticed in their appropriate places. Of the several kinds of perforated communications between the stomach and other viscera now enumerated, the *first* is most commonly the result of abscess in the liver ; although it may arise otherwise in rare instances, as in a case which came under my care where the perforation of the stomach extended far into the substance of the liver. The *second* is also most frequently the result of an abscess opening into the stomach. The *third, fourth, fifth, and sixth*, almost in all cases, are referable to perforating ulceration, cancerous or simple, commencing in the stomach. The *seventh and eighth* forms of fistulous communication are most commonly caused by large gall-stones in the gall-bladder. The *ninth, tenth, and eleventh* most frequently proceed from cancerous or simple ulceration commencing in the stomach or pylorus. The last of these lesions are caused chiefly by the absence of adhesion of the opposite peritoneal surfaces, which adhesion takes place in the others, although it is weaker, or more readily separated, in the cancerous or malignant, than in the simple forms of ulceration. Of these forms of fistulous communications between the stomach and other viscera, *gastro-colic fistula* is probably the most frequent. This form has been ably described by Drs. BRINTON and MURCHISON,

and references have been given by them to interesting cases, published in medical journals, and to preparations contained in the principal pathological collections.

14. ii. VOMITING FROM GASTRO-INTESTINAL FISTULA.—The *vomiting* caused by an *abscess* in the liver, or by abscess from diseased vertebræ, opening into the stomach, or by a communication with *purulent collections* in the pleura or lungs, or in any other situation, may be recognised by the history of the case, and by the purulent characters of the rejected matters. When occasioned by *cancerous ulceration* or *growths*, the vomitings, with the antecedent and attendant symptoms, are described at the places above referred to. But when perforation of the stomach, either from these lesions, or from other ulcerative processes, takes place, then the vomitings frequently assume distinctive characters, which indicate the nature of the mischief. In cases of *gastro-colic fistula* the matters vomited very frequently indicate, or at least render probable, the existence of lesion from either cancerous or simple ulceration. In a very able memoir on this subject, Dr. MURCHISON has adduced 33 cases, of which 21 were caused by cancer, and 9 or 10 from simple ulceration. As to these he remarks, “that the proportion of cases resulting from cancer is more than double that from simple ulceration ; and, as simple ulcer of the stomach is about five times as common as cancer, Dr. BRINTON was not far wrong when he conjectured ‘that its proportion in the malignant disease is at least thrice (and probably six to ten times) as great as in the ulcer.’ This accounts for the fact that some pathologists, as ROKITSKY and BOCK, speak of it as a result of cancer of the stomach, but make no mention of it under the head of simple ulcer.” Had Dr. MURCHISON consulted what I have stated on this subject in the article STOMACH, and in the chapter on “*Ulceration and Perforation of the Stomach*,” he would not have asserted that pathologists “make no mention of it (gastro-colic fistula) under the head of simple ulcer.” This may be true as respects the foreign pathologists whom he has referred to ; but if he will turn to p. 1008 of the *third vol.* of this work he will find, among other remarks pertinent to this subject, the following : “The ulceration may be *cietrized*, as shown in the article just now referred to (§ 39), or it may proceed onward after adhesions have been formed between the opposite portions of the peritoneal membrane, and thus the ulceration may proceed not only to perforation of the stomach, but also to perforation of a contiguous portion of the digestive canal, as the colon, or to more or less ulceration and perforation of another organ ;” and I proceed to farther illustrate the subject, and, in the following paragraphs, to describe the commencement and course of ulceration and perforation of the stomach, the several varieties they present, and the symptoms which they occasion.

15. This greater rarity of gastro-colic fistula, as a sequela of simple ulcer, may, according to Dr. MURCHISON, “depend on three causes : viz., the fact that simple ulcer is much more rarely met with in that part of the stomach nearest the colon—the great curvature (in 5 only of 220 cases) ; and that there is a greater tendency in cancer to contract adhesion to neighbouring parts before perforation ; while, at the same time, the cementing matter is of a less permanent quality than the lymph thrown out in the vicinity of a

simple ulcer." The absolute frequency of gastro-colic fistula, as a sequela of *cancer* of the stomach, can only be approximated. DIETRICH observed this lesion in 6 out of 160 cases, or in 3·75 per cent.; Dr. BRINTON in 11 out of 507 cases collected by him, or in 2·17 per cent. That the ulceration generally commences in the stomach, I have shown in the places above referred to; but I have admitted that it may originate in the colon or other parts, and extend by perforation into the stomach. The cases recorded by Dr. MURCHISON fully illustrate this inference. He remarks that, "Out of the thirty-three cases, there is every reason to believe that the disease commenced in the stomach in twenty-six; in four cases there are not sufficient data for forming an opinion on the point; and in three only does the disease appear to have been most advanced in the colon after death." In cases where tubercular disease or abscess finds its way into the stomach or into both stomach and colon, as in very rare instances, when this result has occurred from disease of the kidney or the gall-bladder, the course of the alteration is manifest.

16. iii. THE DIAGNOSIS of *gastro-intestinal*, or *gastro-colic fistula*, depends chiefly on the characters of the matters thrown off the stomach. The topic is partly discussed, especially as respects the antecedent and many of the existing symptoms, in the articles referred to above; but those phenomena which indicate the presence of this fistula have not been so fully described. *Vomiting* is always present, although it sometimes recurs only at intervals. It is often preceded, and attended, by fetid eructations, or by bilious, dark, or grumous matters in the ejected fluids. When there is a free communication between the stomach and intestine, the vomited matters generally are more or less faecal. But where the fistula is long or circuitous, vomiting of faecal matters may not, or only occasionally, be observed. Dr. MURCHISON remarks that out of nineteen cases in which the history was clear, faecal vomiting was observed in eleven, and fetid—perhaps faecal—in three; and he draws the following conclusions: "1. Faecal vomiting is probably present in all cases in which the opening (except this be very minute) is situated in the fundus, or great curvature, of the stomach, and may also be present when the disease is in the pylorus. 2. In all cases in which food is vomited the opening is at or near the pylorus, so as to preclude the passage of food." In cases of cancer of the pylorus or duodenum, vomiting may be less after the formation of the fistula than before, as the food in the former case may pass into the intestine, into which the fistula opens.

17. Where *gastro-intestinal* or *colic fistula* exists there may be present eructations with a faecal odour, as well as faecal vomitings; or there may be only fetid eructations. Next to faecal vomiting, the presence of undigested food in the stools is an important indication of *gastro-intestinal fistula*. I have long supposed that at least some of the cases of *lientery*, among the many which came before me at the Infirmary for Children, were actually instances of this form of fistula. As the disease advances, as it usually does, to a fatal issue in the course of several days (although it is sometimes prolonged to some weeks or even months, with intervals of partial ease), diarrhoea with undigested matters in the stools soon after they had been taken, or an occasional recurrence

of costiveness, emaciation, anaemia, general cachexia, or yellowness of the body, as described in the articles already referred to, are commonly observed.

18. III. VOMITING AND RETCHING FROM SYMPATHETIC IRRITATION.—Irritability of the stomach, so great as to be attended by vomiting or retching, on receiving all, or most kinds of food or drink into the stomach, is often occasioned by vascular erythsm, inflammation, or organic alterations of an adjoining, or even of a distant organ or part. The vascular excitement of, and determination of blood to the uterus during *pregnancy*, and the death of the foetus in utero in the advanced months of gestation, are often productive of vomitings or retchings; and organic and inflammatory diseases of the uterine organs frequently occasion the same symptoms, especially in delicate and susceptible females, or when those diseases are of an acute or severe kind. As may be readily inferred, inflammations and organic lesions of any of the allied or adjoining viscera very often are productive of vomiting, the rejected matters consisting, as in the preceding diseases, chiefly of the ingesta, and of watery,ropy, and mucous fluids, sometimes coloured with bile, unless when congestion, inflammation, or abscess may give rise to the discharge of blood or purulent matter from the stomach, or from adjoining parts, communicating with the stomach. Enlargements, morbid growths, or other lesions, in the liver, spleen, pancreas, mesentery, omentum, disease of the diaphragm, or of the gall-bladder and ducts; misplaced, or suppressed, or retrocedent gout; suppression of urine, or retention of this excretion, verminous diseases, &c., severally occasion vomitings when they reach an advanced stage of development.

19. In some serious organic diseases of the brain, vomitings sometimes occur, and occasion, in both children and adults, in the latter especially, much difficulty in determining the true cause and morbid relations of this symptom, which, however, may be readily ascertained in most instances from the history of the case, and by estimating the succession and grouping of the accompanying phenomena. Diseases of the stomach itself, especially of the pylorus, duodenum, and of the intestines, particularly of the small, of the liver and gall-bladder—more especially when the concave surface of the liver is much affected—and of the kidneys, are frequently attended by vomiting; and when gall-stones irritate the gall-bladder or ducts, or are passing along the latter, the vomitings and pain are then very distressing. The irritation of calculi in the kidneys, or in their pelvis, or when calculi are passing along the ureters, produces the same distressing symptoms; but the most urgent and dangerous vomitings occur in obstructions of the bowels, especially of the small intestines, from internal or external strangulation, from intussusceptions, from inflammations, or from various mechanical or structural causes of intestinal obstruction, as shown in various places (see *arts. COLIC AND ILEUS, CONCRETIONS, BILIARY AND INTESTINAL, &c.*), more particularly when the vomitings are attended by fetid eructations, and when the vomited matters present a fetid or faecal odour, or a more unmistakable faecal character. In all cases of obstruction, and irritation of any of the ducts and canals within the abdomen, especially when the obstruction is caused mechanically or by a solid

body, the sympathetic occurrence of vomiting is generally very urgent and distressing, although often presenting intervals of comparative ease. In all cases of vomiting and retching, the history of the case should be ascertained as fully as possible.

20. Besides these more strictly local diseases, which are attended by vomitings and retchings, there are several constitutional maladies, especially those adverted to above (§ 18, 19), in which these symptoms are of a most prominent character, and proceed from contamination of the blood, acting both on the frame generally and upon the stomach and its allied viscera in particular. No doubt that in all these maladies, whether the choleric and hæmagastic pestilences, or the contamination occasioning malignant puerperal fevers, or that arising from poisoned wounds, inoculation, &c., the morbid impression is primarily and energetically made upon the organic nervous system, the retching and vomiting often following closely upon it; but nevertheless, this impression being made, the alteration produced in the blood aids it, and promotes both by increasing the depression of the organic nervous force, and by irritating the stomach and adjoining parts, thereby rendering the vomitings of a more serious, dangerous, or obstinate character, as evinced in these maladies.

21. IV. VOMITING AND RETCHING FROM SEA-SICKNESS are common to all persons soon after they feel the motions of vessels on the sea, if they have not acquired an immunity from this suffering by habit.

22. i. DESCRIPTION.—In some, vomiting is preceded by a prolonged nausea, with extreme prostration, faintness, vertigo, and apathy. In others, vomiting takes place more or less quickly, after nausea is first felt; and in many the nausea and distressing retchings, with headache, vertigo, and prostration, continue or return at shorter or longer intervals after the stomach has been completely evacuated, but only if the motion of the vessel continues. When the retchings continue or return after free vomiting, a ropy, mucous fluid, mixed with more or less bile, is evacuated, owing to the emulgent operation of the retchings on the liver, gall-bladder, and ducts, thereby producing a favourable influence on certain diseases noticed hereafter (§ 25).

23. The severity and duration of sea-sickness depend much upon the susceptibility of the individual, and the extent of motion to which he is subjected; and, although generally all persons are liable to sea-sickness on first going to sea, yet its severity and continuance are great in proportion to weakness and delicacy of constitution. Usually, however, the sickness either subsides or ceases altogether in a few days; and in previously healthy persons it is followed by a good or craving appetite, and a return of health, although the cause of the suffering may continue. Many persons who, from frequent or prolonged voyaging, have become exempt from sea-sickness, at least while at sea, experience a recurrence of it when they return to sea, after having passed a considerable time on land; but it is usually of short duration, or slight in these persons. Sea-sickness occurring during a short passage, as in crossing the Channel, immediately ceases with the stillness of the vessel, or on landing, vertigo only remaining for a time. Some delicate persons, who are very susceptible of sea-sickness,

are also liable to nausea and vomiting from the motion of a carriage, especially while they remain inside, but escape from the sickness when they ride outside.

24. ii. PROGNOSIS. — Sea-sickness, although mentally and physically most depressing, and although both vomitings and retchings are most severe, is generally unattended by danger, and it very rarely terminates fatally. When this event takes place, it is more the consequence of the continued nausea, and of the loathing of all kinds of ingesta, owing to their inducing retchings, and of the resulting inanition, exhaustion and fatal sinking, than of any alteration of structure, or contingent lesion, produced by the severity of the retchings. In all cases where this species of sufferings is prolonged by severe weather, and susceptibility or peculiarity of constitution, more or less debility, exhaustion, inanition, anæmia, and loss of flesh are observed; but generally, as soon as the cause ceases, or even considerably subsides, as on the occurrence of fair weather after storms, or on landing, these effects soon disappear, and are often followed by restored health, or even by an improved state of health, owing to the circumstance noticed above (§ 22).

25. iii. THE NATURE OF SEA-SICKNESS has been a subject of frequent discussion. The brain, the heart, and the cerebro-spinal nervous system generally, have been severally referred to as the seat of this distressing disorder. That these are more or less affected during its continuance—that the brain and nervous system are impaired in volition and in the vigorous discharge of all their functions, mental and physical, cannot be doubted; and that the heart acts feebly, although sometimes rapidly, but without tone or vigour, is equally manifest, until the retchings and vomitings occasion more or less reaction, accompanied with perspiration, which varies with the severity of the sickness and the constitution of the patient. But the affection of these—of the cerebro-spinal nervous system and of the vascular and muscular systems, with the organs and parts more immediately concerned in the act of retching—is the necessary result of the effect produced by the motion of the vessel upon the semilunar and allied ganglia, and the viscera they endow with the organic nervous force. This effect continues until retching and vomiting supervene and occasion more or less reaction, according to the constitutional powers of the sufferer. That the primary influence of the vessel's motion on the semilunar and allied ganglia is depressing may be inferred from the distressing sense of sinking referred to the epigastric region, and from the general physical and mental prostration preceding the retchings. That vomiting and retching, each varying in grade and character, follow very powerful depressing influences, is shown by the effects of most sedative and exhausting agents—whether poisonous, morbid, or infectious—which act more especially or immediately on organs or surfaces endowed by the organic nervous force. It may, therefore, be inferred that the vital depression produced by the vessel's motion is the chief cause of the sickness and vomiting, the irritation caused by matters contained in the stomach during this depression merely aiding in developing the retching and vomiting, this act and the evacuation of the stomach affording a slight temporary relief, the depression and sickness still continuing more or less, or for a period, according to

the continuance of the cause, and to the constitution and predisposition of the sufferer.

26. iv. THE REMEDIAL INFLUENCE OF SEA-SICKNESS is sometimes remarkable in several diseases, more especially when the sickness is attended by free vomiting, the appetite returning afterward, and when the patient does not suffer inordinately, or when the suffering is not long continued. In severe *hooping-cough*, especially in persons near or past puberty, and even in infants and children, sea-sickness is often of marked advantage. In this complaint the patient, sufficiently protected from exposure or weather, may be placed in a rowing or sailing boat, when much swell of the sea is observed, and carried out to sea, until vomiting takes place, when a return to land may be directed. In other cases and circumstances, a short voyage in sailing vessels furnishing the requisite accommodations, may be taken with benefit. A similar advantage may accrue in cases of *tubercular consumption*, as I have shown in that article (§ 420); in *hæmoptysis*; in *spasmodic asthma*; in *chronic bronchitis*; probably in some cases of *chronic diarrhœa* and of *dysentery*, when suitable accommodations are afforded, and in *torpid states of the liver*, &c. In these cases, the influence of nausea in lowering vascular action and removing spasm, and the action of retching and vomiting in emulging the biliary apparatus (§ 21), and in evacuating mucous accumulations in the bronchi, are of essential service. By this action, also, congestions of the lungs and liver are removed, or are aided in their removal, and a healthy secretion of bile promoted—circumstances of great importance in several pulmonary, biliary, hypochondriacal, gastric, and intestinal diseases.

27. v. THE RETCHINGS AND VOMITINGS which may be viewed as idiopathic or primary, and which are not necessarily connected with inflammation or structural disease of the stomach and allied viscera, although they ultimately, by persistence in their cause, become thus associated, are those which take place in the morning, and which either recur frequently or habitually, and which the patient generally removes for the time with a glass of brandy, or of brandy and water, or of some other favourite liquor. In these cases, morning sickness is the result of exhaustion from previous over-stimulation, and for a time is merely functional, but sooner or later it becomes more and more structural. The same form of sickness often follows in the morning heavy suppers, either with or without excessive drinking. The circumstance of a person complaining of sickness or vomiting habitually or frequently in the morning, and more especially if he have recourse to spirits to remove it, before any food can be taken, is most positive evidence of such person being an incurable drunkard, although he may never have been intoxicated.\*

\* The following cases will illustrate this: A young man in a large wine-merchant's house, and having free access to extensive wine vaults, was seized, after habitual sickness and vomiting in the morning, with most violent pain in all the smaller joints, and especially in the wrists and ankles. He came under my care, when he confessed that sickness and vomiting every morning upon getting out of bed had continued for three or four years; that it was instantly cured by a glass of brandy, but that he could take little or no breakfast. As soon as he returned to business in the morning, he continued drinking at intervals sherry or port wine, or brandy, as either came in his way, and he thus took from two to three bottles of wine, besides brandy, every day, unless Sunday, when his supply was not so liberal. He recovered his health,

The form of disorder may be considered as allied to *vomiting from sea-sickness* (§ 21, *et seq.*), the most idiopathic form of vomiting.

28. When the functions of the stomach are exhausted by the excessive excitements of intoxication, or by the irritation of indigestible or unwholesome food, and more especially by the ingestion of substances which readily enter into the acetous, the lactic, or the vinous fermentations, when received in the weak and exhausted stomach, then pain, vomiting, or eructations are produced by the gaseous products, by the acidity, and by the various irritating matters and combinations resulting from the fermenting substances, which, if they fail in undergoing these processes during the imperfect digestion, experience putrefactive changes, and occasion the same, or even more serious and more obstinate disease.

29. When the digestive processes are impaired or exhausted, owing to general debility (*see that article*, § 15, *et seq.*), or to inordinate muscular or mental exertions, or to local or constitutional disease, the articles of food most prone to undergo fermentation, as bulky vegetables, raw fruits, fermented bread and liquors, &c., produce an increase of disorder, by the fermentation which ensues, and the frequent repetition of such disorder at last passes into more serious disease, which is characterized by recurrences of retching and vomiting, and by gastrodynia, whenever such disease is aggravated by the ingestion, or commixture of fermentative substances. The connexion of fermentation in the stomach with indigestion and vomiting, has been well discussed by Dr. TURNBULL, and although the doctrine of fermentation has been pushed too far by him, there can be no doubt of the importance of giving due consideration to changes of this nature, which certainly take place in the digestive canal, when the nature, the quantity, and the admixture of indigestible, saccharine, and putrescent substances are taken into the stomach during functional or structural lesions of the digestive organs. Persons addicted to the excessive use of intoxicating

relinquished this habit, and he has for very many years been sober and temperate. He never evinced any symptom of disease of the stomach or liver, and he is the only instance I can recollect of a complete reformation from drunkenness.

A cook in my family was always sick and retching in the morning, and could take no breakfast. Her principal meal was supper; soon after which she retired into her own room, and nothing was known of her until she had partly recovered from her sickness and resumed her morning duties. Upon hearing this I became alarmed at the probable consequences of her after-supper indulgence, and means were devised to prevent her apartment from being fastened on the inside, and then she was there found drunk. These cases are not of unfrequent occurrence; but in some instances vomiting is only occasionally present, chiefly in the morning—a chronic diarrhœa, sometimes passing to a fatal dysentery, with diseased liver, taking its place.

Several cases of very young persons, mostly females, who have died from the excessive use of spirituous liquors have been brought under my notice. These were characterized by habitual sickness and retchings in the morning, which were allayed by the accustomed stimulus or by strong tea, but followed, after a longer or shorter period, by enlarged and fatty liver; or by emaciation, chronic diarrhœa or dysentery, with ulcerated bowels; or by the most violent pains in the extremities, of a mixed neuralgic and gouty or rheumatic character, terminating in several of the cases before the age of twenty. In one fatal case, at the age of 17, the growth was remarkably stunted owing to this vice, all the others who had commenced it at an early age being very much under size. In this instance the fatty liver filled almost the whole abdomen, and descended deep into the pelvis, and produced an abdominal enlargement as great as the full period of pregnancy.

liquors experience more or less fermentation in the stomach after the excitement caused by these liquors has subsided; and the products of the fermentation, acting on the exhausted organ, frequently produce that amount of irritation which is manifested by nausea, retchings, vomitings, and gastrodynia, and which the drunkard relieves by a recourse to the accustomed stimulus.

30. VI. VOMITING ATTENDED BY THE DISCHARGE OF THE SARCINA VENTRICULI.—In 1842 Professor GOODSIR described this remarkable production, and since that time many cases of this kind have occurred, most of which have been either observed or referred to by Dr. TURNBULL, of Liverpool. I have not observed more than three instances of this production in the substances vomited since attention was first directed to it, and these occurred in cases of organic disease of the stomach, in which the fermentative and putrefactive processes appeared to have been readily produced. The writer just mentioned has noticed thirty cases of *sarcina ventriculi* recorded by various authors, and has himself observed six. Of these eighteen had terminated fatally. He arranges these cases in four groups: "1. Cases in which ulcers or eicitricies arising from them, or some other non-malignant disease of the stomach, obstructed the pyloric orifice. 2. Cases of cancerous disease contracting the pylorus. 3. Cases in which there was no disease of the stomach itself, but displacement or some other condition obstructing the pylorus. 4. Cases in which the disorder may have been functional, recovery having taken place more or less perfectly." The analysis of these cases furnishes the following: the disease is more common in males than in females, in the proportion of twenty-four to ten, and between the ages of thirty and fifty. Of the three cases which I saw two occurred in confirmed drunkards between forty and fifty-five years of age. In all the cases vomiting was the prominent symptom; flatulent distention, offensive eructations, pain in the stomach, costiveness, emaciation, and anæmia being also present. According to Dr. TURNBULL, the sensation of "something alive in the stomach" was also experienced, but this was not remarked in any of the cases for which I was consulted. Dr. B. JONES found the urine alkaline, and this excretion has, in some instances, contained oxalate of lime and sugar.

31. VII. TREATMENT.—i. TREATMENT OF SYMPTOMATIC VOMITING AND RETCHING.—It is manifest that the treatment of retching and vomiting can only be successfully accomplished by a strict examination of the history of each case, and of its causes, extrinsic and intrinsic; and by ascertaining the particular category of causes to which each individual case should be referred; whether the vomiting has been occasioned, 1st, by the ingestion of an injurious or poisonous substance (see POISONS); 2d, or by the invasion or accession of a febrile, exanthematous, or pestilential malady; 3d, or by disease of the stomach or bowels, or of some adjoining organ or part; 4th, or by sympathy with the irritation or structural lesion of a more remote organ; 5th, or lastly, by the abuse of intoxicating or stimulating liquors.

32. A. If the vomiting be caused by poisonous ingesta, it is obvious that the means advised in such cases in the article now referred to are required, conformably with the evidence obtained as to the nature of the poisonous substance which

has been taken. To this extensive subject I can add nothing to what I have adduced in the article POISONS.

33. B. If there appear any reason to ascribe the vomiting to the invasion of an exanthematous, infectious, or pestilential malady, especially when any such is prevalent or epidemic in the same locality, or when the vomiting is associated with shivering or any of the other symptoms of the invasion of any of these maladies, then the treatment advised for the accession of such malady ought to be adopted. (See the treatment recommended on the accession of the CHOLERIC, and HÆMAGASTRIC PESTILENCES, of SCARLET FEVER, SMALL-POX, &c.)

34. It should, however, be recollected that the vomitings accompanying marked vital depression, especially those occurring in, or characterizing pestilential and malignant maladies, and in animal or fish poisons, and in contaminated states of the blood, admit not of being cured, or even mitigated, by depressing or sedative remedies, whether narcotic or anodyne, unless exhibited in small doses, and conjoined with stimulants, aromatics, and cordials. Opium, morphia, and their preparations, hydrocyanic acid, chloroform, and hydrochloric ether, will produce little benefit unless they be given in the manner now stated. In these cases, opium and hydrochloric ether, when judiciously combined with other means, will sometimes be of service; but the hot spices, warm stimulants, and cordials, prescribed in large doses, according to the malignancy of the case, will be found the most efficacious. Thus large quantities of capsicum, brandy, and of other powerful stimulants, have been retained by the stomach in malignant and pestilential maladies, while sedatives and narcotics have been instantly rejected by it; and even the spirits of turpentine have been retained, both in these maladies and in the last stage of low fevers, as well as in similar states of disease, especially when the blood is contaminated and vital depression is extreme. I have seen these effects in numerous instances since 1817, when I first employed these substances in the hæmagastria pestilence or yellow fever. In all these diseases the usual means of allaying vomiting had failed, and increased the vital depression, the sense of sinking and mental apathy, and therewith the vomiting; which symptoms generally terminated in a fatal pumping up, or rejection of the contents of the stomach, without retchings, but often with singultus, when sedatives and narcotics were employed.

35. C. It is obvious that the vomitings and retchings caused by inflammatory and organic lesions of the stomach and allied viscera can be allayed only by means which will remove or alleviate the disease of which the vomitings are merely a symptom. In the less severe of these a temporary aid may be obtained from the use of hydrocyanic acid, from opiates given with oleaginous demulcents and nitrate of potash, or the muriate of ammonia in very small doses, and from external derivatives. But creasote and the more heating substances, often of service in the opposite states of vomiting, are seldom of service in these. In cases of intestinal disease the remarks now made are equally applicable; and where strangulation or obstruction from any cause exist in, or otherwise implicate, the intestinal canal, the removal of it is essential to the removal of the vomiting. (See arts. COLIC and

ILEUS, CONCRETIONS, BILIARY and INTESTINAL, DIGESTIVE CANAL, STOMACH and INTESTINES, INFLAMMATION and ORGANIC LESIONS, &c.)

36. *D.* The retchings or vomitings caused by irritation, inflammation, and organic lesions of distant organs require careful examination and discrimination; and although these sympathetic vomitings are often allayed, especially by demulcents conjoined with refrigerants and sedatives, or with hydrocyanic acid, or creasote, opiates, &c., yet the treatment should be mainly directed to the particular disease, or structural lesion, of which vomiting is a distressing symptom, whether it be seated in the brain, in the kidneys, uterus, or other part. When the irritating cause is a calculus, or concretion in the gall-ducts or bladder, or in the urinary apparatus, the means advised for these, under their respective heads, and warm anodyne fomentations, tepid or warm baths, are those which are most appropriate, although these may be conjoined, or alternated, with those which are most serviceable in allaying the vomiting (§ 34). Creasote is often of much benefit, when the stomach itself and its allied viscera are free from inflammatory and organic disease, and when the retchings are purely sympathetic; but it soon fails as a palliative when the primary or chief disease has not received due attention, or when it remains unsubdued. Moreover, creasote, when given in too large or frequent doses, is apt to increase inflammatory action when it exists, especially if it be of a sthenic or plegmonous character. When the vomiting is attended by manifest asthenia, or vital depression or exhaustion, creasote, as well as stimulants, aromatics, and cordials, are frequently very beneficial.

37. *E. The vomitings, &c., attending pregnancy*, especially in the earlier months of this process, will often be palliated or prevented by the above means—by the combination of the alkaline or earthy carbons with infusions of columbo, cascarilla, and with tinctures of the same tonics, and with the addition of hydrocyanic acid, or small doses of opium, or of chlorodyne. In this class of cases fermentation often accompanies the sympathetic irritability of the stomach, and develops this latter state into the act of retching or vomiting. In the more obstinate and severe cases, or when these means prove inefficacious, then creasote in pill or in mixture, combined, according to circumstances, with opiates, alkalies, &c., should be prescribed.

38. *ii. TREATMENT OF SEA-SICKNESS.*—This is a very hopeless subject, yet it is nevertheless one which should not be abandoned, for with care and judgment sea-sickness may be more or less alleviated and its duration abridged. The usual means employed for it are seldom of service and often tend to prolong the nausea, without ultimately preventing the vomiting. It is generally preferable, when the sufferer is young or even moderately strong, to partake of such food and drink as he may prefer, thereby to prevent ineffective retchings; and when free vomiting is accomplished, to take small and frequent doses of a suitable anodyne, in small quantities of fluid. Substances of large bulk, or even in moderate quantity, or gaseous fluids, by distending or filling the stomach, generally bring back the retching and vomiting. During the nausea, or even after it is moderated, the stomach is quite incapable of digesting alimentary substances; there-

fore their presence in the stomach acts only as an irritant of the weak and susceptible organ, and in a short time brings back the sickness and vomiting. Having, therefore, promoted a free evacuation of the stomach, in the way now advised, small doses, often repeated, of either hydrocyanic acid, or tincture of opium, or chlorodyne, or of chloroform, or of hydrochloric ether, may be given in small quantities of a demulcent mixture, which may be made agreeable by the addition of a few drops of an aromatic cordial. Creasote has been recommended, but its odour is disagreeable to many persons; but, when prescribed for sea-sickness either in the form of pill, or in a demulcent mixture, it should be given in small doses, or not exceeding half a minim for a dose, which may be repeated according to its operation. The demulcent and anodyne medicines may be given in any of the mint waters, especially when the patient is distressed by flatulence and eructations, and any cordial or aromatic may be added if sinking at the epigastrium or vital depression be experienced.

39. Females and delicate persons, subject to sea-sickness, should retire to their cabins immediately on embarking, if the voyage be likely to be longer than a few hours, or to continue during the night. Unless the sufferer be weak, or extremely depressed by the sickness, retchings, and vomitings, it is generally preferable for him to keep up and struggle against his enemy, as he will be the more likely to overcome ultimately, and to shorten the duration of the attack. If he have any return of appetite after vomiting, it should be indulged in great moderation, the food being the most digestible within his reach; if sickness and vomiting recur, they will generally be of short duration, and be followed by a return of appetite, which, if prudently indulged, will be generally followed by health. This plan is to be preferred if a long voyage, or one beyond three or four days be anticipated; for by that time, or not much longer, the evil will cure itself. It is only for the more severe cases, or in short voyages, or for delicate females and weak persons, that the medical treatment advised above (§ 38) is either much required, or particularly appropriate.

40. *iii. TREATMENT OF RETCHINGS AND VOMITINGS CAUSED BY DRUNKENNESS AND BY FERMENTING INGESTA.*—The drunkard generally knows well how to remove the morning effects of his previous indulgence, and he finds the recurrence to his accustomed liquor, or to one still more energetic, to be the most efficacious remedy. But he counts not the ultimate cost, viz., according to the nature of the liquor indulged in, organic disease of the stomach, pylorus, liver, &c.; or chronic diarrhœa, or dysentery, delirium tremens, &c., often complicated with the foregoing. Safer remedies for retchings and vomitings consequent upon DRUNKENNESS are the aerated waters, the compound decoction of aloes with cinnamon water, creasote in pills or in mucilaginous mixtures, and the means advised in the article now mentioned (§ 15, *et seq.*). When the vomitings are of daily recurrence, it is evident that the only permanent cure is to subject the patient to such restraint as may be legally permitted, seeing that he is incapable of restraining himself. This is, however, one of those forms of moral degradation against which the laws have no provision, and for which medical aid is rarely

of any avail, especially as regards prevention or permanent cure—

"Ille cum hominibus, non cum Diis agitur."

41. Vomitings caused by *excessive fermentation* in the stomach are generally allayed by medicines which either arrest or neutralize the process, or develop the vital force of the organ, or allay excessive irritability of it, or which operate in more than one of these modes. The sulphite of soda, the alkaline carbonates, the carbonates of magnesia or of lime, calcined magnesia, the citrate of magnesia, the sub-nitrate of bismuth, the biborate of soda, are severally of use in these cases, especially when prescribed in conjunction with tonics, stimulants, and anodynes, and sometimes with narcotics. As the fermentation and the vomitings are generally attended by impaired organic nervous force, as well as by irritation of the digestive mucous surface, tonics and stimulants are required for the former morbid condition, while anodynes, especially hydrocyanic acid, or small doses of opium, or of opiate preparations, or of the lupulus, or of hyoseyanus, are appropriate for the latter. In many instances, in addition to a frequent recourse to certain of the above, in varying combinations, other substances which are calculated to remove irritation and to check fermentation, and at the same time to promote a healthy secretion from the stomach, liver, and duodenum, may be given from time to time. Of these the most beneficial are Hydrargyrum cum cretâ, the pilula hydrargyri, and calomel, and these, according to circumstances, may be given in full doses with opium, creasote, the preparations of hop, &c. Small doses of the nitrate of potash, or of the hydrochlorate of ammonia, given with hydrochloric ether, in mint water, &c., are also beneficial in these cases.

42. In all cases of *retching and vomiting*, referable either to the *abuse of intoxicating liquors*, or to *extreme dyspepsia attended by vomitings*, or to *gastric fermentation*, or to *pregnancy*, attention should not be directed alone to the morbid condition of the stomach, for the vomitings or retchings will not be permanently removed, or they will be liable to recur after a time, if the biliary and gastro-intestinal secretions and excretions be not duly promoted. In all such cases, therefore, having palliated the vomitings, a moderate action should be kept up on the bilio-intestinal functions; and the means which I have most frequently employed have been the hydrarg. cum cretâ, or blue pill, or Plummer's pill with soap taken at bed-time, once or twice in the week, and the following draught early on alternate mornings, or every morning, or at bed-time:

No. 279. R Potassæ Bicarb., gr. xij. ad xvij.; Ammonia Carbonatis, gr. vj.; Tinct. Sennæ Comp.; Tinct. Cardamom. Comp., aa, ʒj.; Infusi Sennæ Comp., ʒss.; Infusi Gentianæ Comp. ad ʒjss. Misce, et sit Hæustus.

To this draught may be added, according to the peculiarities of the case, a dose either of hydrocyanic acid or of the extract of taraxacum.

43. iv. VOMITINGS ATTENDED BY THE REJECTION OF THE SARCINA VENTRICULI are generally the result of protracted indigestion, attended either with fermentation or with organic disease, malignant or otherwise, of the stomach or pylorus (§ 80, *et seq.*). In the majority of these cases the means already advised may first be employed, and if these fail, as they often will in this form of complaint, other more energetic medicines should be prescribed, generally in efficient combinations,

viz., camphor, creasote, and small doses of opium, made into pills, with any suitable powder, and with either common tar (pix liquida) or the balsam of Peru. These having been taken for a time, the exhibition of tonics with alkalies, or alkaline carbonates and hydrocyanic acid; or of the sulphites, or the pyroxylic spirit, or limewater, or the chlorides, may be tried, conjoined with preparations of either cinchona or cascarilla bark, or with an infusion or decoction of cedar or pomegranate bark.\*

44. v. DIET IN CASES LIABLE TO VOMITINGS, &c.—*Vomitings*, when palliated or removed, present the greatest difficulties as to the selection of alimentary substances. As a general rule, all such as are liable to readily undergo any of the fermentative processes should be avoided. But most alimentary substances undergo one or other of these processes, whether of an acid, or of a putrefactive, or of a saccharine nature, when mixed with the morbid secretion of the stomach, and when the organic nervous force of this organ is much impaired. Still there are aliments which are much less prone to undergo these changes than others, although much depends upon the peculiar idiosyncrasy of the patient. Frequently the food which the patient most desires in these cases, or for which he feels a relish, will be found the most easily digested or retained. Substances which readily undergo fermentation, as fermented new bread, vegetables, raw fruit, the ingestion of varieties of food, and fermenting liquors should be avoided. In this subject, however, I can add nothing to what I have advanced in the article on INDIGESTION. (See § 55, *et seq.*)

BIBLIOG. AND REFER.—*Hippocrates*, Opp. p. 1080. (*Vom. nigra*).—*Celsus*, l. ii. c. 13.—*Oribasius*, Synopsis,

[\* We present some of the *Formule* which we have found most successful in allaying idiopathic vomiting:

i. R Catechu, ʒi.; Columbo, grs. xxx.; Winter's Bark, grs. xx.; Boiling Water, fl. ʒiv. M. Digest for eight hours; strain, and add Sirup of Red Roses, fl. ʒj. M. In tea-spoonful doses, repeated ʒro re nata.

ii. R Powdered Columbo, ʒiv.; Opium, grs. iv.; Oil of Peppermint, gtt. x.; Sirup sufficient. M. Beat into a mass, and form thirty pills. Give two-three times a day in spasmodic vomiting.

iii. R Columbo, ʒss.; Boil in Water, liij. to five fl. ʒ.; strain, and add Carbonate of Potassa, grs. x.; Lemon Juice, fl. ʒij.; Tinct. of Opium, gtt. xii. M. A tea to a table spoonful every hour as an anti-emetic.

iv. R Creasote, gtt. j.; Camphor Water; Comp. Infus. Gentian, aa, fl. ʒvj. M. A tea-spoonful occasionally.

v. R Tinct. of Opium, fl. ʒss.; Decoct. of Starch, fl. ʒiv. M. For an enema in obstinate vomiting.

vi. R Burgundy Pitch, ʒij.; Yellow Wax, ʒss.; Powdered Cinnamon, ʒj.; Oil of Pimento; Oil of Lemons, aa, ʒj. M. Melt the resin and wax together, and strain; when they begin to thicken, on cooling, mix in the cinnamon previously rubbed with the oils, and make a plaster. This plaster over the stomach will very generally relieve nausea and vomiting, and relieve gastric uneasiness when nausea is not present.

vii. R Bicarbonate of Soda, ʒjss.; Powd. Gum Arabic, ʒj.; Oil of Mint, gtt. lv.; White Sugar, ʒj.; Carbonic Acid Water, ʒiv. M. A table-spoonful occasionally; very useful.

viii. R Powdered Ipecac., grs. ij.; Carb. of Soda, grs. x.; Sirup of Poppies, ʒj.; Mint Water, ʒvj. M. In tea-spoonful doses, to check spasmodic vomiting.

ix. R Infusion of Spearmint, fl. ʒvj.; Burned Brandy, ʒj.; Paregoric, ʒj.; White Sugar, ʒss. M. A table-spoonful every fifteen minutes.

x. R Licarb. Potassa, ʒj.; Powd. Gum Arabic, ʒj.; White Sugar, ʒj.; Seltzer Water, ʒvj.; Tinct. of Camphor, gtt. xi. M. A tea-spoonful frequently.

A strong mustard cataplasm over the epigastric region will often prove more successful than any internal remedies. These cases, however, must not be treated empirically, but always in reference to the pathological cause.]

CLASSIF.—I. CLASS, I. ORDER. (See Preface.)

1. DEFIN.—*Animal parasites are independent organized beings, descended from peculiar animal parents, which require, in order that they may be enabled to complete their development, growth, or reproduction, to take up abode either constantly or temporarily in or upon a second animal organism of a different kind, from which they also derive their nourishment. Human parasites are those which select the human body as this second organism.*

2. The above definition is a modification of that given by Dr. KÜCKENMEISTER, in the very able translation of his work *On Animal and Vegetable Parasites*, by Dr. LANKESTER. LEUCKART (*Parasiten und Parasitismus*, in VIERTODT's Archiv, 1852) remarks, that whenever "an animal is too small and too imperfectly armed to overcome and destroy another living being upon which its instincts direct it to seek for nourishment, it must be contented with robbing it, by feasting upon its blood, juices, and solid parts." As respects the human body especially, it would be more correct to state that, whenever the vital force of this body is reduced by disease, inanition, and exhaustion, it is then exposed to the invasion of those parasites which are peculiar to it; and that these parasites are developed and multiplied with a rapidity generally in proportion to the diminution of vital force or of vital resistance to their invasion and multiplication. The only animal parasites which appear in or upon the human body belong to the classes of insects and worms, and probably also to the infusoria. "As far as we know, these parasites of man are not subject to the attacks of secondary parasites." Many of them are common to man and other mammalia, while others are peculiar to him.

3. It has been very justly remarked by Dr. LANKESTER, in his excellent and instructive preface to the work just referred to, that the study of animal parasites involves questions of the highest scientific and practical interest, and that it teaches that, though scientific theories may sometimes be barren of immediate practical results, they cannot fail to free the mind from prejudices which lead to erroneous practice, and even to disastrous results. On this ground, therefore, he refers to some apparently of the least practical topics, with the hope of assisting the reader to understand those generalizations which the subject of animal parasites involves. But however barren the consideration of the generation and reproduction of organic beings may at first sight appear to be, it is of the utmost importance in respect of its ultimate or practical results; and Dr. LANKESTER has done medical men a great service in furnishing them with a succinct and correct summary of the results of the recent researches of Dr. KÜCKENMEISTER and others as to this subject, especially as regards the history of the human entozoa. Dr. LANKESTER justly remarks that, although it was easy to account for the existence of intestinal worms, by referring it to the ingestion of their eggs, yet a difficulty presented itself regarding hydatids, which evidently had an independent animal existence. Hydatids exhibited no sexes, they produced no eggs, and readily supported the theory of "spontaneous, or equivocal generation." Even as this theory was driven successively from

every other part of the animal and vegetable kingdoms, it "found refuge among the strange and paradoxical creatures imbedded in the tissues of man and other animals, far removed from any external influences." The time has, however, at length arrived when it can be demonstrated that the cystic worm is no longer to be regarded as the result of a "fortuitous concourse of atoms," but that it is the offspring of the tape-worm, undergoing one stage of its growth, through which it must pass before it can attain to the more dignified development of its parent. In many cases the cystic worm has the power of developing, at this stage of its growth, a large number of creatures resembling itself, and these have, each of them, the power of developing themselves into tape-worms. "The cystic worm—let it be an *Echinococcus*—has originated from the egg of a tape-worm, the embryo of which has found its way from the stomach and intestines, through their walls, into the tissues of the body. This worm consists of a vesicle or bag, to which is attached a head, called the 'scolex.\*' In *Cysticercus*, the hydatid of the pig, there is but one scolex, but in *Echinococcus* there are many scolices. Now this scolex, or scolex-head, as it is sometimes called, is the stock or germ—the head—from which all the segments of a tape-worm proceed. The cyst of *Echinococcus*, then, has the power of producing a large number of these heads, each of which may grow into a tape-worm. The cyst—the original cyst of the worm—is, in the language of STEENSTRUP, 'a nurse.' KÜCKENMEISTER and the Germans call it a mother cyst. But this cyst will produce not only scolex-heads, but other cysts like itself. These are 'daughter cysts;' and these secondary cysts will also produce scolex-heads. They are also 'nurses;' and in virtue of their existence the mother cyst becomes, in the language of STEENSTRUP, a 'parent nurse.' The second cyst may contain, as it frequently does in the *Echinococcus altricapariens* of KÜCKENMEISTER, a third cyst—a 'grand-daughter cyst,' which is also a 'nurse,' and thus on." (LANKESTER, in *Preface to his Trans. of KÜCKENMEISTER, &c.*)

4. Neither these cysts nor scolex-heads have any sex. Nor do they acquire sexuality as long as they remain in the flesh in the hydatid condition; and to this state of the worm Professor HUXLEY applies the term "*agamozoid*." In order to acquire the conditions necessary to the development of sexual organs, the cystic form of the worm must be followed by another animal. "The scolex-head then becomes, in its turn, truly a 'nurse,' and this of a most prolific kind; for, the cysts below being displaced, the numerous segments ('proglottides,' as they have been called) begin to make their appearance. The conditions are now such, that sexes appear; each segment is merely a capsule containing a male and female generative apparatus, and nothing else. Eggs, the result of the union of sperm-cells and germ-cells, are now produced in myriads. These pass into the external world, and, being swallowed and digested, set free the embryos, which again

become cystic, as above described." (*Op. cit.*, p. xiii.)

5. These phenomena are not peculiar to *entozoa*. STEENSTRUP observed them in the *medusæ*, the claviform polypes, the salpæ, and the trematode entozoa. Professor OWEN has also adduced similar cases, in the exposition of his views on "Parthenogenesis," or the successive production of procreating individuals from one ovum, or asexual reproduction. Not only are there some among the lowest animals, in various stages of development, capable of producing buds, or individuals like themselves, without sexual union, and embryo-bearing eggs, but there are also among the *articulata*, both in the *crustacea* and *insects*, females producing eggs, which proceed to the development of perfect animals without any sexual intercourse, or union of sperm-cells and germ-cells. Such a phenomenon is so opposed to the general opinion as to the necessity of sexual intercourse for the development of the embryo in the higher animals, that many have not hesitated to express their disbelief in it. Dr. LANKESTER thus expresses himself respecting it: "Regarding, however, the phenomena of reproduction from the point of view afforded us by the *entozoa* and other forms of lower animals, we must receive the facts in both cases equally cautiously, and judge according to the evidence. VON SIENOLD, in his work on 'True Parthenogenesis,' affords good evidence for believing that the queen bee deposits two kinds of eggs, the one of which has come under the influence of the sperm-cells of the male, and the other not. A very curious point in this history is the fact that while both eggs produce young bees, the impregnated eggs produce worker or female bees, while the unimpregnated eggs produce male or drone bees. In a recent communication to the Royal Society, Mr. LUBBOCK has shown that species of the entomotracheous crustaceous genus *Daphnia* produce living young in all respects like their parents, without any sexual intercourse. It would appear, then, that up as high as the most developed forms of articulate animals, we have evidence that there is no real difference between the functions of reproduction and generation."\* (*Op. cit.*, p. xiv.)

#### 6. I. THE ORIGIN OF ANIMAL PARASITES, more

\* Dr. LANKESTER, for the better understanding of these and other general remarks he has offered, has subjoined the following diagram:

GENESIS.		
Growth.	Reproduction.	Generation.

\* The word "Scolex"—σκόληξ, Worm, or Spuiwurm, Germ., or round worm, was employed by MÜLLER to designate, generically, imperfectly-developed forms of tape-worm. "The head was the most characteristic part of these creatures, and gradually the term 'scolex' was applied to the heads of all forms of cystic or tape worms. The term *scolex* has now no generic signification, as the creatures to which it was applied were immature forms of other genera." (LANKESTER, in *Preface, &c.*)

especially of the worms which often infest the human body, has long been a subject of speculation among naturalists and physicians. One class of writers believed that these parasites, at least many of them, originated in the endowment of animal molecules with vitality from the parent body, favoured by certain states of the vital forces of that body, the states originating their organization also promoting their growth and propagation. Since the progress of microscopic research consequent upon the improvement of our instruments, this doctrine, which till then had been gaining ground, has received a signal overthrow, chiefly at the hands of German helminthologists. VON SIEBOLD, one of the most recent and of the ablest of these, remarks on this topic, "that he has gradually arrived at the conclusion that these parasites do not originate by 'equivocal generation' from substances of a dissimilar nature; and physicians and naturalists thought themselves justified in assuming that the parasitic worms in the intestines of men and animals owed their origin to ill-digested nutriment, or that they were developed in the most widely different organs from corrupt juices. They took it for granted that certain morbid processes in any organ were competent to give rise to parasites, assuming that the elementary constituents of an organ affected by disease, separated themselves from their natural connexion, and not perishing, but transforming themselves into independent organisms, became parasites. It was certainly more convenient thus to speculate than to endeavour to attain, by patient researches and careful experiments, a secure insight into the hidden workings of nature. It was by the latter method that the hitherto unanticipated development of the sexual apparatus was discovered in many parasites, such as round worms, thread-worms, tape-worms, and flukes, in which such an immense mass of eggs and young can be generated, that it seems unnecessary to look farther for their origin. As to tape-worms, it is well known that a single individual is often composed of many hundred joints. Each joint is capable of laying many hundred ova, so that the number of the progeny of a single tape-worm is enormous. Dr. ESCHRICHT, of Copenhagen (*Das Physische Leben in Popularen Vorträgen*; Berlin, 1852; p. 112-115), possesses a tape-worm expelled by a patient of his, which consists of 1000 joints; and some of the joints contain more than 1000 ova. According to this writer, a careful examination of the reproductive organs of a female *Ascaris lumbricoides* shows the number of ova to be innumerable." (VON SIEBOLD, *Op. cit.*, p. 4.)

7. The precise mode in which such an immense brood of these parasites make their way into the interior of animals was long imperfectly understood. It was, however, ultimately ascertained that intestinal worms undertake emigrations in order to reach that animal whose organs are fitted by nature for their habitation. VON SIEBOLD states that the young of the tape-worm (which inhabits the intestine of the higher animals only) "leave the place where they were brought forth, or laid as eggs (that is to say, they emerge from the intestine of their parent's host), and seek an opportunity to enter into the intestine of some other creature. It is easy to convince one's self of the emigration of the tape-worm, by examining the excrement of animals infested by them, at those times of the year at which they attain their

sexual maturity. We then observe that sometimes single joints, or connected series of joints, full of ova, sometimes immense masses of the ova, are passed with the fæces. The same thing holds good with regard to the ova of the *Distomata* that infest the livers of our ruminating animals; their eggs, after they have been transferred from the liver to the gall-ducts, being washed out with the bile into the intestine, and evacuated with the dung. These emigrations of the young of the intestinal worms benefit not only the creatures they infest, but themselves. There are many kinds of intestinal worms in whose eggs the embryo is never hatched, if they remain in the place where they have been laid."

8. The description (German like) given of the accidental but frequent ingestion or passage of the ova of parasites into other animals, and the dignifying of this passage into an emigration, as if it were an act of instinct, imparts an air of imagination to what is nevertheless the fact of the frequency of this passage, and of its consequences. This writer states that these parasites "must wander to some other place in order to develop their young, or to allow of the escape of the young already developed in them. The young must then either wait for, or seek, an animal to lodge in, having entered into which, they are capable of attaining sexual maturity. By such emigrations the infested animals are at the same time freed from guests whose increase would be both troublesome and prejudicial. For example, what would happen if the millions of eggs that a single round worm or tape-worm can produce were developed and generated in the same intestine in which they were laid? Would not the intestine, after the young had attained their full growth, and brought forth others in their turn, become at last so choked up as to disable this part of the digestive apparatus, so that the whole organism of the unhappy animal must perish along with his parasites!" (*Op. cit.*, p. 5.)

9. These emigrations and immigrations of the young of intestinal worms, or, in less imaginative language, this discharge and passage of their ova from and into other creatures, are very important, though long an unregarded part of the history of their propagation; and numerous facts have been discovered showing that the origin of intestinal worms in the viscera of animals can be readily accounted for according to natural laws, without recurring to the mysterious hypothesis of "equivocal generation." An important circumstance favourable to the preservation and passage of the ova of parasites into animals in which they become developed is the hardness of the shells which envelop them. Owing to this the germ or embryo of many of them are protected from external injury, and their vitality preserved for many months, and until circumstances admit of their development. After leaving the dwellings of their parents the ova pass into privies, drains, dust-heaps, &c., where, surrounded by more or less moisture, and subjected to various grades of temperature, and contained in manures, and spread on fields and meadows, they are, either in the state of ova or in that of more advanced development, taken with various articles of food into other animals, or they are washed by rains into streams or brooks, and are swallowed in the drink. Many of the young intestinal worms, according to VON SIEBOLD, more or less developed, but still enclosed in their egg-shells, remain quite

inactive in their passive emigrations, and it is of course a mere chance whether they reach their goal or not. The young of others, having left their egg-shells, may take a more active share in the process, creeping out of their holes and corners in wet weather, or in damp mornings, upon plants or grass, and enter animals suited for their habitation and development with the food. By preventing sheep from being driven out in the morning till the dew is off the grass, or from grazing in wet swampy pastures, these animals are so far protected from *Strongyls* and *Distomata*. The origin of the thread-worm, known as the *Filaria insectorum*, that lives in the bodies of adult and larval insects, could not be accounted for, and was referred to equivocal generation; especially as they contained no trace of sexual organs. But VON SIEBOLD ascertained that they were not true *Filaria*, but belonged to the peculiar family of thread-worms, comprising the genera *Gordius* and *Mermis*; and that these parasites wander away when full grown, boring their way from within through any soft part of the body of their host, and thus creeping out. "These parasites do not emigrate because they are uneasy, or because the caterpillar is sickly, but from that same internal necessity which constrains the horse-fly to leave the stomach and intestine of the horse where he has been reared; or which moves the larva of the gad-fly to work its way out of the boils on the skin of oxen. The larvæ of both these insects creep out in order to become chrysalises, and thence to proceed to their higher and sexual condition." Now this desire to emigrate is implanted in very many parasitic insect larvæ, and the perfect full-grown, but sexless thread-worms of insects, are in like manner moved by this desire to wander out of their previous homes in order to enter upon a new period in their lives, which ends in the development of their sexual organs.

10. As some kinds of parasites that have emigrated are never met with below a certain size, so some kinds that have already made their way into the interior of animals are not to be found under a certain size. It is known that many parasites do not enter into the animals in which they are to pass through their farther stages of growth, until they have attained a certain degree of development elsewhere. This is particularly the case with such intestinal worms as remain parasitic in the last stage of their existence, viz., that of sexual maturity, while the *Gordiacæ* quit their parasitical life, in order to become sexually mature away from the animal they have infested. During these early wanderings, the worms in question, VON SIEBOLD remarks, commonly undergo a change of form, often accompanied by other phenomena of so highly remarkable and abnormal a character as to render their metamorphosis or phases of existence almost incomprehensible. By degrees a mass of observations of remarkable metamorphoses of intestinal worms accumulated and formed a complete chaos of seemingly irregular phenomena, until the Danish naturalist, STEENSTRUP, succeeded in evolving a certain order out of this confusion, by the discovery therein of a hidden underlying law of nature, by which all the phenomena that had seemed so devoid of plan could be reduced to order. He named this law the "*Alternation of Generations*," and advanced two points of difference between it and *metamorphosis*; the first is,

that the young of those animals which come under the former term are not only unlike their parent at first, but remain so; the second distinction is, that this young generation, so dissimilar to the parent animal, brings forth new creatures, which either themselves or their descendants revert to the original form of the first parent. Whereas, in simple metamorphosis, the dissimilar young pass by gradual changes into the likeness of the parent animal, and until this metamorphosis is complete are incapable of generation. Thus in the alternation of generation the parent animal produces dissimilar young, which STEENSTRUP terms "*nurses*," whose descendants only take her form. "A most important circumstance which characterizes these *nurses* or '*Agamozooids*' physiologically is, that they bring forth young without themselves possessing any real sexual apparatus. Those agamozooids, in fact, multiply by division, by external or internal gemmation; they develop within their bodies germs which become new creatures. But these germs do not deserve the title of eggs, nor is the place where they are developed to be called an ovarium, since the germs which VON SIEBOLD distinguishes by the name of '*sporule*' are not only devoid of the ordinary constituents of an ovum, a vitelline membrane, yolk, germinal vesicle, and so-called germinal spot; but the farther development of the germ-body is not preceded by those conditions which are essential to the development of true ova within an ovarium. The organ in which, in certain agamozooids, the '*geminae*' are formed, cannot, therefore, be properly termed an ovarium, and I shall distinguish it by the name of '*sporularium*.' No '*nurses*' present any sexual distinctions, and hence their method of multiplication and propagation, which takes place by means of sporule formed within sporularia, or by ordinary budding, or by division, must be arranged amid the modes of asexual reproduction." (VON SIEBOLD, *Op. cit.*, p. 13, 14.) I must refer the reader to what this writer farther remarks on the topic of alternation of generation, especially as it occurs among the *Trematoda* and *Cercariae*.

11. From his researches, VON SIEBOLD infers that certain sexually matured Trematoda—*Monostomum*, *Distomum*—generate young within their sexual organs, which are not developed into sexual individuals similar to their parents in form and structure; but that each embryo is converted into an animal of remarkably different form—into a *Cercaria*-sac, which has the nature of a sexless nurse, since, without possessing sexual organs, it nevertheless generates young *Cercariae*. These *Cercariae* again differ from their parents, but gradually become sexually perfect, and in form and structure take the likeness of their grand-parents. If we follow these *Trematoda*, which are subject to the alternation of generations, in their wanderings, we shall find that they meet with many obstacles to the completion of their developmental course, which is the entering into the viscera of an animal in which they can become sexually developed. The destruction of the various forms of *Trematoda*, by the untoward circumstances to which they are liable, is compensated by the fact that they are furnished by the alternation of generations with the means of greatly multiplying the various developmental stages of their descendants—a sufficient number of individuals always remaining out of the numerous young of the

nurses and larvæ, which achieve the propagation of their species.

12. The history of the *Cercariæ* explains many phenomena erroneously interpreted by the supporters of the doctrine of equivocal generation. It was difficult to understand how living entozoa could have originated in the viscera of animals, sometimes in organs deeply seated or cut off from all external communication, and could there propagate their kind; the mode of origin—by equivocal generation—assumed for them apparently accounting for the circumstance of these entozoa being unprovided with sexual organs. Frequently, also, young or imperfectly developed intestinal worms were met with in the substance of organs, and were attributed to equivocal generation, "though in reality these *entozoa* were in the act either of emigrating, or immigrating, or else were tarrying until the creature they infested should be swallowed by some other animal, when the passive immigration for which they waited would take place. Many wandering parasites are unresistingly suffered to bore their way into and remain in the organs of animals, while certain kinds are stopped by becoming enclosed in a coagulable lymph thrown out by the organs they traverse." There are two kinds of cysts connected with parasitic worms: in the one the cyst is thrown out by the parasite itself, as in the case of the *Cercariæ*; in the other, the organ in which the encysted parasites lie imbedded furnishes the walls of the cyst. In such cysts or capsules are found the most diverse kinds of intestinal worms, whose farther course may be very various. "Many of the encysted young of intestinal worms experience no farther change, but only remain for a longer or shorter period until such time as they may, together with their host, pass into the intestine of some animal of prey suitable for their future development. To this kind belong the *Cercariæ* already mentioned. There is also a small, imperfectly developed, round worm, hitherto always erroneously described as a perfect intestinal worm, under the name of *Trichina spiralis*, which remains a long time in its cyst without either growing or developing sexual organs. This minute *Trichina spiralis* is met with not only in the substance of the muscles of man, but also in the pleura and peritoneum of the most widely different kinds of vertebrate animals, enclosed in oval capsules about a quarter of a line in length." After a certain time of confinement is allotted to this little worm, and its deliverance not effected, it dies and undergoes a process of calcareous degeneration, its form being altered or entirely destroyed. Other encysted intestinal worms succeed in obtaining nourishment through the walls of their prison, and thus go on growing. Those, however, which are intended by nature to attain their sexual maturity only in the digestive organs of certain animals cannot arrive at this condition in their cysts, and must, notwithstanding their farther growth, fail in the attainment of the power of sexual propagation, until the animal they inhabit is devoured by the predaceous creature whose intestine is alone fitted to allow of the passage of these asexual intestinal worms into the last stage of their development. (VON SIEBOLD.)

13. From what has been stated we gather that those young intestinal worms which are developed at a distance from the nidus of their parents succeed, in the end, in reaching those situations

where they may repeat the part of their progenitors, and reproduce their kind. The embryo parasites that have only just left their eggs disperse in all directions, so that they may immigrate into other animals, whenever an opportunity offers. Many thousands of these embryos of necessity never attain their object, owing to the numerous casualties they are liable to. However we may accept the facts displayed in the researches of VON SIEBOLD and others, it by no means follows that the emigration or immigration of these parasitic animals is the result, as they suppose, of instinct. The parasite having arrived at the full stage of sexual development produces numerous ova, many of which necessarily are so circumstanced, by situation, dissemination, &c., as to admit of their passage through the different phases and metamorphoses of evolution and development; but that these changes, and the emigrations resulting from the circumstances common to all or most of them, admit of the inference that instinct has any thing to do with the phenomena; or that their temporary or continued residences, their journeys or passages from one place or animal to another—their migrations, &c., proceed from their possession of this endowment or principle, or that their migrations and residences are otherwise than altogether *passive*, cannot be received or credited without farther evidence. But, after thus stating a disbelief of the instinctive faculties of these parasites, the facts connected with their propagation and evolution become practically of importance.\*

14. Instead of viewing the migrations of the embryo or young parasites as passive, and the accidents connected therewith as equally so, VON SIEBOLD considers the former as altogether instinctive, and the latter as stray migrations. But, while altogether disbelieving that instinct has any thing to do with the matter, this writer's views deserve consideration. The point of most importance, he remarks, is "that these embryos should select, as their temporary residence, such creatures as will be consumed by those animals, whose intestines served their parents as a habitation and birthplace for their young. But many of these young, immigrated, intestinal worms will die without reaching the last stage of their development, in consequence of their host and involuntary carrier escaping from his natural enemies. Again, many embryos will be led astray

\* If we understand by the *instinct* of animals that unknown faculty or endowment implanted in their constitution by the Creator, by which, independent of instruction, observation, or experience, and without a knowledge of the end in view, they are impelled to the performance of certain actions tending to the well-being of the individual and the preservation of the species, there is as much reason to believe that the minutest organisms in nature are as perfectly controlled by it as the largest. That it is not infallible in either is evident from the fact that both are sometimes at fault, and commit mistakes; but then these errors are quite as frequent among the one class as the other. Indeed, facts would seem to establish that insects, and even worms, are endowed with a much more exquisite and flexible instinct than the larger animals. Such pliability to circumstances, such adaptation of means for accomplishing an end, as is observed in the bee, the spider, the ant, the silk-worm, the moth, the caterpillar, the locust and its larvæ, &c., can nowhere be found among birds, fishes, or any of the higher species of animals below man; and the same remark, we think, will apply to human entozoa and ectozoa in all their varied conditions and modes of existence. No one can read "An Introduction to Entomology," by KIRBY and SPENCE, one of the Bridgewater Treatises, without being convinced that instinct is more strikingly manifested in the insect tribe than in any other class of animated nature.]

by the migratory impulse (!), and pass into animals which never become the prey of those whose digestive canal is their goal." The embryos which thus "fail in their object" are here viewed as "strayed parasites;" and VON SIEBOLD remarks that "the *Trichina spiralis*, which is found in human beings, and which must be regarded as an encysted sexless nematoid worm, can hardly have found its way into the muscular structure of man, except by having gone astray: so also the *Cysticercus cellulosæ*, which not unfrequently appears in the muscles and other organs of man, and which is an asexual tænioid agamozoid. The *Cysticercus cellulosæ* changes to a sexual tape-worm in the intestinal canal of certain mammals; the *Trichina spiralis*, after transportation to another and more favourable situation, will also become sexually developed." Many of the young of the intestinal worms, which only attain the last stage of their development in the digestive canal of the *vertebrata*, are said, by this writer, to pass, in the course of their wanderings, into the wrong organs [their instincts, I may infer, have not yet been fully developed or perfected!]; for instance, into the muscular substance, the liver, or the peritoneum; here they remain undeveloped, while other individuals of the same brood, which have found their way into the intestines of the same animals, arrive at maturity. "The *Triænophorus nodulosus*, infesting fishes, offers an example of this, developing into a long sexually mature tape-worm, in the intestines of pikes and perch, while at the same time these fishes often harbour other tape-worms, which are, however, always sexless, in cysts in their liver. These last must certainly be also regarded as strayed parasites."

15. VON SIEBOLD believes that, in the bodies of vertebrate animals, the small embryos of intestinal worms bore their ways not unfrequently through the walls of the blood-vessels, and fall into the current of the circulation, and are carried thus to distant parts. Embryos of intestinal worms, to which the term of hæmatozoa has been given, have often been discovered in the blood of birds, reptiles, and fishes. These hæmatozoa never increase in size, nor become farther developed in the blood, but often stick in the small blood-vessels of organs, which afford a more congenial soil for their farther growth; and hence appear, on some occasions, worms in the brain, in the spinal marrow, and in the eyeball of man and animals. The *Cysticercus cellulosæ*, the *Cænurus cerebri*, and the *Echinococcus hominis* and *veterinorum*, have been occasionally found in these situations, and have served as an argument for the doctrine of equivocal generation; [also the *Filaria*.] "With the migrations and alternation of generation among the intestinal worms two other phenomena are connected, which were formerly quite unnoticed, but which now have been generally observed. In the vicinity of those sexually perfect intestinal worms which, in their wanderings, are subject to the alternation of generations, only eggs, or recently-hatched embryos, are met with; but the farther stages of development are always wanting, since they first make their appearance after the emigration of the young to other places. Farther, many of these intestinal worms, taken while in the act of migrating, are never found below a certain size, since they do not commence their wanderings, either as nurses or larvæ, until they have already

reached a certain stage of their development." (*Op. cit.*, p. 30.) Would it not be more correct to view these evolutions of parasites from germs and ova, and their passages, or passive migrations, during their development, as accidents connected with the numbers generated, and with the locations and transitions of the embryos—their development and sexual perfection being results of favourable circumstances which happen only to a few of the many generated—instead of viewing these migrations and their consequences as events produced by the instinctive endowment which VON SIEBOLD has conferred on these parasites? While the possession of this endowment by these animals may be disputed, the facts adduced by this writer, respecting their origin, development, and alternation of generations, are more deserving belief and consideration.

16. II. THE CLASSIFICATIONS OF INTESTINAL WORMS have been so numerous and so different the one from the other, that an attempt to place them before the reader would not be consistent with my limits and with expectations of utility. Recent researches, also, have thrown doubts on the principles by which the older arrangements were guided; and the orders, *genera*, and *species* of *entozoa*, which have been found in the animal kingdom, are so numerous as to prevent even a brief notice of them at this place. I must, therefore, refer the reader to the more recent works enumerated in the BIBLIOGRAPHY, and especially to those of Dr. JOY and M. FELIX DUJARDIN. Dr. KÜCHENMEISTER has given a classification of animal and vegetable parasites, which, as far as it refers to the *human entozoa*, I shall, with some alterations, adopt.

17. I. Class, INFUSORIA.—II. Class, VERMES, HELMINTHIA.—i. Order, PLATYELMIA.—A. Sub-order, *Cestodea*. (a) Genus, *Bothriocephalus*. (b) Genus, *Tænia*.—B. Sub-order, *Trematoda* or *Trematodea*. (a) Genus, *Monostoma*. (b) Genus, *Distoma*.—ii. Order, NEMATELMIA.—A. *Trichocephalus dispar*, *Trichina spiralis*.—B. *Oxyuris vermicularis*.—C. *Strongylus gigas*, *S. longigginatus*.—D. *Ancylostomum duodenale*.—E. *Ascaris lumbricoides*.

18. 1st Class.—THE INFUSORIA are destitute of high organization. They are simple, vitalized, membranous structures, which live by mere endosmose. The *vibriones*, the *bursaria*, *monads*, and *bodones* "are a peculiar attribute of fermenting and putrefying fetid animal substances, or always presuppose a half-dead soil, and do not derive their nourishment so much from living substances as from matters which the living body has expelled, or are in the course of expelling as foreign to it; they are properly only to be regarded as indirectly parasitic upon the human body." FICINUS found sluggish bean-shaped infusoria 1-1000 to 1-1500 of an inch, and sometimes double this size, and of a globular form, in the perspiration of the feet, on the places where the epidermis was thrown off, as well as on the moist folds of the skin in young children; and others have met with them in purulent and foul secretions from the vagina, urethra, bladder, putrescible urine, &c.

19. i. *Trichomonas* (DUJARDIN). *T. vaginalis*.—"Corpus nodulosum, gelatinosum, lacteum; cauda brevis; flagellum corpore triplo longius. Motus vacillans. Longit. 1-222." This parasite occurs only in women with gonorrhœal discharge, or with an abundant vaginal secretion containing

mucous and pus globules, and never in a healthy vaginal secretion. KÖLLIKER and SCANZONI found it in the vaginal—never in the cervical—secretion of both pregnant and unimpregnated women, especially in the creamy and acid secretion, sometimes in the neutral, but never in the alkaline. Owing to its resemblance to the mucous corpuscles, it has been confounded with them. The body of this parasite is 0.01 to 0.018 millim. in length; the flagellum, 0.028 to 0.03 millim. in length; and furnished with 4 to 8 short cilia, in continual movement, which facilitate its recognition. The capability of infection by these infusoria has not been determined, although very probable.

20. ii. *Denticola hominis* (FICINUS). “*Genus valde dubiosum*” (KÜCHENMEISTER).—This parasite, according to FICINUS, is an aciliated infusorium, with the mouth on the ventral surface, and probably furnished with a carapace, resembling the *paramesia* and *kolpoda*; but he considers it more allied to the *monodes* and *vibriones*. The genus he believes to be numerous; and he infers that every mammal has its peculiar species. Dogs and horses, he says, next to man, exhibit these infusoria in abundance. He states that he found them especially in the interstices of the molars; more rarely on the mucous membrane of the mouth, scarcely in the saliva; but most abundantly where the teeth have been neglected, and in hollow teeth. They adhere, form filaments, and advance between the teeth and gums, pushing between the roots of the former and the latter, destroying their union. These effects are, however, prevented and remedied by the usual operations on the teeth, and by aromatic, tonic, astrigent, and antiseptic dentifrices.

21. 2d CLASS.—a. VERMES, HELMINTHA, are of the greatest importance to both the pathologist and the practical physician. The parasites belonging to this class are destitute of many of the organs possessed by the higher animals. They have no distinct respiratory organ; the oxygen necessary to their existence can only be taken up in their fluid food. Hence they are enabled to exist within the human body, either in its closed or open cavities, or in its tissues. “They constitute the true entozoa, and furnish no representatives to the series of human *Epizoa*, although some of them may be destined, in the course of their development, to pass a portion of their lives in water, or perhaps (as in the case of the *Cercaria*) as epizoa upon other animals. Sexual organs may always be detected in those specimens of these animals which have attained their last grade of development.” The senses of sight, smell, and taste are wanting in all these parasites, but their sense of touch appears to be highly developed. The intestinal canal is wanting in the *Cestodea*. In the *Trematoda* it forms a cæcal canal, in which the mouth also performs the functions of the anus; while in the *Nematodea* it becomes a complete alimentary canal, with a mouth, œsophagus, stomach, intestine, and anus. In the tissues of the *Cestodea* is a tendency to the formation of an envelope of a calcareous nature, which is wanting in the *Trematoda* and *Nematodea*. These three kinds of true HELMINTHA are characterized, 1st. By a general sense of touch; 2d. By a vascular system, of four longitudinal lateral canals in the *Cestodea*, and of a fine network of vessels in the *Trematoda*, which are less distinctly marked in the *Nematodea*; 3d.

By a muscular system, composed of transverse and muscular fibres, without transverse striæ; 4th. By the structure of the epidermis, which consists of a homogeneous finely checked substance, closely approaching the character of chitine; 5th. By the property of giving off a strongly refractive, albuminous substance, in oleaginous drops, when in contact with water; and, 6th. By their scarcely effecting their development without a passive and active migration of their embryos and immature young.

22. b. As to the last of these characters, KÜCHENMEISTER, more rationally than was stated, as shown above, by VON SIEBOLD, remarks that “His migration itself is passive during the embryonic state, and as long as the embryos are still enclosed in the egg-shells or envelopes, during which period they usually emigrate once, passively, into the external world, generally with the excrements of the hosts of their parents; and then again, passively in general, into the intestinal canal of the animal in which they are to acquire a higher development. From the latter moment commences their active migration, by which they seek the situations, usually external to the intestinal canal, in which they are to undergo their metamorphosis into the next higher step or steps of development, which is generally accompanied by an encysting process. Finally, as a general rule, at least as regards the trematoda and cestoid worms, they must afterward migrate, passively, once more into the intestine of the animal in which they are to attain maturity; that is to say, they must pass with the food of their new and final host into its intestine.” (*Op. cit.*, p. 4.)

23. c. General pathology shows that the worms cannot effect their active migration without causing some irritation of the regions through which they pass, whether this migration is performed by the youngest brood, as is usually the case, or by the more or less mature animal, as rarely occurs, and chiefly among the *Nematodea*. The passive migration of all immature parasites into the human intestine takes place without any perceptible morbid phenomena.

24. d. The general prognosis of this class of parasites may be stated as follows: 1st. The young animals engaged in their migration are the most dangerous; 2d. Next to these, the migrating mature individuals, which inhabit the intestinal canal, produce the most dangerous symptoms; 3d. The animals which reside in cysts or closed cavities can become dangerous only when they attain an enormous size; but, when small, they may be present without doing any mischief; 4th. Most of the mature individuals are more accessible to curative means than those of lower stages, especially those which live outside the intestinal canal.

25. e. The principles of treatment for the *Helmintha* are, 1st. The destruction or removal of the mature worms, and of their progeny; 2d. The observation of a rational prophylaxis, founded on the modes of life and migrations of the immature individuals; on the constitution and circumstances, and the habits and modes of life, of people subject to these parasites; and on a knowledge of the nature and peculiarities of the situations in which these plagues are endemic.

26. III. The animals of which I have now to treat belong to the first sub-class of DIESING—*Helmintha achæthelminthica: animalia erectebrata, inarticulata* (i. e., *extrematibus articulis nullis*

*prædita*), nunc molia, aut elastica, ebranchiata, setis retractilibus nullis. I have, following VOGT, VIRCHOW, and KÜCHENMEISTER, divided this class into two divisions: i. *Platyelmia*, flat worms; and, ii. *Nematelmia*, round or thread worms; and again dividing the first section or order into, 1st. The *Cestoidea*, VOGT; the *Cephalocotylea*, DIESING; or the *Platyelmia colonias exhibentia*, or flat-worm colonies, of KÜCHENMEISTER; and, 2d. The *Trematoidea*, VOGT; *Myzelmia*, DIESING; or *Platyelmia isolata*, isolated flat-worms, KÜCH.

27. i. Order, *PLATYELMIA*.—*Entozoa solitaria aut composita, androgyna. Corpus depressum vel teretiusculum, molle, organis ad fixandum aptis præditi. Anus nullus; canalis cibarius aut divinus (rarissime simplex), aut nullus. Cavitas corporis non distincta. Metamorphosis in plerisque; larvæ gemmiparæ aut sporoliparæ.* (LEUCKART.)

28. A. Sub-order, *CESTOIDEA*.—*Cephalocotylea, DIESING; Platyelmia composita, aut colonias exhibentia, Plattwurm-Colonien, or flat-worm colonies, KÜCHENMEISTER; Bandwürmer, tape-worms—Animalia tomotoca, per longum plerumque tempus larvæ nutrice juncta et una cum ea corpus elongatum, articulatum, polymorphum formantia. Larva (Scolex, vulgo caput) pyriformis, foveis aut oculis suctoris quatuor vel duobus instructa, sæpissime uncinata. Proles sexualis (Proglottides, vulgo articuli) organis externis destituta, embryones uncinatis armatos gignentes. Canalis cibarius nullus.* (LEUCKART.)—*Quinque varæ inveniuntur in us metamorphoses: 1. Animal maturum (Proglottis); 2. Embryones uncinati (Grand-nurse, Grossamme); 3. Scolex passivam vitam agens sub forma vermis cystici seu Cysticeera, sub forma Platyceera, et sub forma Acerca; 4. Scolex activam vitam agens (Nurse, Amme); 5. Strobila.*

29. It is only recently that the *cystici*, or *hydatus*, have been shown to be only a stage in the development of the *Tæniæ*, and not to be a distinct family among the *Helmintha*. HIPPOCRATES, ARISTOTLE, and many anatomists and physicians up to the times of REDİ and HARTMANN—in 1683-5—regarded the *Cysticeeræ* as *hydatus*; but the distinct animal nature of these was not recognised until the work of REDİ appeared, and not fully established until the researches of TYSON were communicated to the Royal Society in 1691. (*Philosoph. Transact.*, No. 193, p. 506.) PALLAS, in 1766, stated that all cystic worms are forms of tape-worms, and belong to a single species—“*Tænia hydatigena*, cystic tape-worm”—which only presents some differences, especially in the caudal vesicle, according to the animal it inhabits. But neither TYSON nor PALLAS, by the terms *Tænia hydatigena*, or *Lumbricus hydropicus*, given by them to cystic worms, expressed any opinion as to the genesis of these worms, or their derivation from ordinary tape-worms. GOEZE, in 1780, and WAGLER, advanced but little the views of TYSON; and, although the subject of cystic worms was considered by ZEDER and RUDOLPHI, it made no progress in their hands. At last, in 1842, STEENSTRUP's theory of the alternation of generations made its way, he believing that the cystic worms were early steps in the development of helmintha, which were unknown to him. In 1845, in consequence of STEENSTRUP's discovery, DUJARDIN first asserted that the cystic worms were undeveloped animal forms, and young states of tape-worms; and that they

were produced from those germs of tape-worms which, instead of the intestine, had got into the parenchyma of the body of their host, and, under the influence of this unusual dwelling-place, had advanced to the abnormal state of development which is called a “cystic worm.” Simultaneously, VON SIEBOLD, in Germany, expressed the same opinion with DUJARDIN in France. At first, however, VON SIEBOLD inclined towards STEENSTRUP's view, and said: “In its form, its suckers, and its circle of hooks, the head of the asexual cystic worms possesses such a striking similarity to the heads of certain tape-worms, that one is tempted to believe that the cystic worms are nothing else than undeveloped and larvæ-form tape-worms.” He subsequently, nevertheless, arrived “at the most decided conviction that the cystic worms are strayed tape-worms which have remained undeveloped and become degenerated, and of which the body grew out in the foreign soil into a vesicle, without developing sexual organs.”

30. In 1850, VAN BENEDEN, the Belgian zoologist, declared the vesicular worms to be larval-like, or young states (*scoliecs*) of *Tæniæ*, and compared them with the larvæ of *Tetrarhynchus*. According to him, the head of the tape-worm (*scolex*) is produced from the egg of the tape-worm. If an egg of a tape-worm reaches the intestinal canal of an animal in which it may be farther developed without interruption, the jointed mature tape-worm (*strobila*) immediately grows from the egg in uninterrupted succession; but if it does not reach an intestine of this kind, a longer or shorter period of rest ensues in the farther development as soon as it has arrived at the evolution of the head of the tape-worm (*scolex*); in this case the anterior part of the head sinks into its inflated hinder part, and it becomes a *Cysticercus*, or a cysticercal animal form. KÜCHENMEISTER, however, finds two errors in this inference. 1st. It is not proved that a tape-worm can pass through all the phases of its development in the intestines of its host; and, 2d. And just as little as the caudal vesicle is produced subsequently by dropsical degeneration (DUJARDIN and VON SIEBOLD), does the ready-formed head sink into its inflated hind part, in order to become a *Cysticercus*.

31. As GOEZE had suggested in 1780, KÜCHENMEISTER, in 1851, administered various cystic worms to different animals. For this purpose the latter selected the *Cysticercus pisiformis* of the rabbit, and also the *C. fasciolaris*, and gave the former to the dog and the latter to the cat, and in the intestines of both these animals he “succeeded in rearing *tæniæ* rapidly approaching maturity.” From these experiments he makes certain deductions, of which the following are the most interesting: 1. The caudal vesicle occurs in all individuals of all species of cystic worms, even though they live in the most various zones and different animals. 2. The universal loss of the caudal vesicle has its analogue in the metamorphosis of many animals. 3. All cystic worms, in the earliest period of their existence, have the head constantly inverted towards the caudal vesicle. 4. The state of rest in which the cystic worms must live in the interior of their caudal vesicle, in order to their development, would be inconceivable, if they had to collect the nutritive fluid for themselves, and did not contain it in them. 5. The cystic worms are not strayed dropsical tape-worm nurses, but tape-

worm larvæ furnished with a provisional organ (caudal vesicle), probably being a reservoir of nourishment, and incapable of sexual multiplication, for which there is neither room nor sufficient nutritive material. 6. The cystic worms constitute a necessary step in the development of the *Tænia*. 7. We cannot speak of dropsy or degeneration, and not even of straying, because we do not yet clearly perceive how the brood could get to the dwelling-place of the cystic worm. And, 8. *Cysticerci*, when transferred to the intestines of other animals, do not become developed into jointed tape-worms, unless the species of *Cysticercus* is suited to the intestines of particular animals; thus, the *Cysticercus pisiformis* was not developed in the intestines of the cat, but it was fully developed in those of the dog. KÜCHENMEISTER asserts that all eminent German zoologists now agree with him in believing "that every cestode worm, and not merely the *Tænia*, pass through a cysticercal state; that the cysticercal larva lives in various parenchymatous organs, and the free *scolex* (*strobila*) usually in the intestine of a different host; and, lastly, that the tape-worm head (*scolex*) is produced in the interior of the previous embryonic body (i. e., the caudal vesicle), and remains enveloped in this until it gains the situation for which it is ultimately destined."

32. But to place beyond all doubt that the cystic worms were necessary steps in the development of *Tænia*, it was also requisite to prove their production from the embryos of the tape-worm brood. "It is true that the six characteristic embryonal hooklets have not yet been detected upon true vesicular worms, but we shall shortly see that the laws of analogy, as well as experiment, afford us a glance into this process." After various experiments, KÜCHENMEISTER proceeds to state that he resolved to resume those experiments with the *Tænia Caninus* in order to obtain the remarkable phenomena of the vertigo in sheep. On the 15th of May, 1853, he obtained the cystic *Canini*; on the 25th of July mature proglottides of the *Tænia* were passed by the dog to which the *Canini* were administered; and these, in order to make the experiment under the most unfavourable circumstances, were administered to a perfectly healthy two-year-old wether, a description of sheep which are usually free from *Canini*. On the 10th of August the sheep was vertiginous; and on the 13th it was necessary to kill the animal; and in the brain he found fifteen young vesicles of *Caninus*, partly on the surface of the brain, which was reddened by inflammation, partly in the substance of the brain, and even in the ventricles. In January, 1854, six lambs were fed with *Tænia Caninus*. Of these five became vertiginous in about eleven days. LEUCKART fed, in October, 1853, a colony of white mice with *Tænia crassicolis*. In January, 1854, he examined his mice, and found them infested by cystic worms. KÜCHENMEISTER subsequently proved that, by the administration of mature species of *Tænia*, as far as they were accessible to him, to suitable animals, only the cystic worms belonging to these species can be reared; but not any kind of cystic worm at pleasure. From the concordant experiments of HAUBNER, LEUCKART, VAN BENEDEN, MÖLLER, and himself, KÜCHENMEISTER considers that this much is established:

33. "1. Mature *Tænia* have hitherto been rear-

ed successfully from all vesicular worms administered when a suitable host was selected; thus, from *Cysticercus pisiformis* the *Tænia serrata vera* was obtained; from *Cyst. tenuicollis*, the *Tænia ex Cyst. tenuicollis*; and from *Caninus cerebri*, the *Tænia Caninus*; all three in the intestine of a dog; from *Cyst. fasciolaris*, the *Tænia crassicolis*, in the intestine of the cat; from *Cysticercus cellulosa*, the *Tænia solium*, in the human intestine; from *Echinococcus velerorum* (*Scoliciparicus* of KÜCHENMEISTER), a *Tænia Echinococcus*, in the intestine of a dog; and from *Cysticercus longicollis* *Hyperdæi*, the *Tænia crassiceps*, RUD., in the intestine of the dog (LEUCKART)."

34. "2. From the eggs of *Tænia solium* in pigs, from those of *T. Caninus* in sheep and cattle, of *T. serrata vera* in rabbits, of *T. crassicolis* in rats and mice, of *T. ex Cysticercus tenuicollis* in sheep and lambs, the corresponding vesicular worms have been reared. The experiments with the eggs of the *Tænia* of *Echinococcus* have hitherto remained unsuccessful."

35. Up to a recent period it was the most general opinion, still entertained by some, that the tape-worm (tape-worm chain) was a simple animal, with numerous segments. Nevertheless, some older physicians correctly perceived the tape-worms were not simple, but compound animals. By many the several segments of *Tænia* were regarded as separate worms; and when DUJARDIN has recently called *proglottides* are described by them in the human tape-worms as "*Vermes cucurbitini*." At the same time they fell into the great error of not regarding the chain as produced by a successive formation of joints placed one behind the other from the head, but expressed the remarkable opinion that the tape-worm was produced by the adhesion of the individual "*Vermes cucurbitini*" one after the other, by which means the many-jointed worm was formed. The opinion that the tape-worm was a compound animal—an animal composition—was first expressed by LEUCKART. Soon afterward, ESCHRICHT and STEENSTRUP expressed this opinion more strongly, and VAN BENEDEN proved it, after DUJARDIN had described the segments of tape-worms which occur isolated, as peculiar animals, under the name of *proglottis*.

36. i. *The mature Animal, or Proglottis* — "From the moment that the hindmost segment or segments of a tape-worm colony has become so far developed as to contain the six-hooked brood ready formed and enclosed in the egg-capsules, this segment seeks to break loose, either by itself or in company with several others, in order to continue an independent existence, either in the same place (the intestine of its previous host) or in a different one (in the external world). All this varies according to the species. In *Tænia*, *Tetrarhynchus*, &c., each joint usually breaks loose; in *Bothrioccephalus*, a series of joints." In those in which no regular formation of segments exists, no single proglottides or segments can break loose, but only single brood-places, or fragments of the body of the cestode worm with such brood-places; or the eggs must escape singly. The proglottides have for the most part a flat quadrangular form, very similar to the *Trematoda*, and usually a white or yellowish, rarely a reddish or brownish colour; they have neither mouth, anus, nor intestine. "As the eggs possess a much greater diameter

than the vagina, they cannot pass through this, but can only escape out of the proglottis when the vagina acquires a larger opening, by tearing, &c. This takes place sometimes even in the intestine of the first host, and the eggs escape separately into the outer world with the excrements, which then appear as if sprinkled with fine white sand; or immediately without the intestine, where the progress of the proglottis is seen indicated by a white milky streak. Sometimes the proglottis does not burst in either of the above-mentioned places, but gets uninjured into the intestine of a new host, in which case it distributes its brood only after it has been destroyed by digestion. According as the eggs reach the intestine of their host in this way separately, or enclosed in the proglottis, and therefore in a mass, solitary or numerous specimens of a cystic, or of the analogous state, are produced within one and the same host." The proglottides thus perform an *active* migration from the intestine of their previous host, and are *passively* or contingently transferred into the intestinal canal of a new host. With the dissemination of their brood their function ceases.

37. ii. *The six-hooked Brood, enclosed in separate Egg-capsules.*—These are called eggs, although their development differs greatly from that of ordinary eggs. The embryos enclosed in the egg-shells are globular naked vesicles, unlike their parents; the smallest of them measure only 0.022 mill., and the largest 0.05. They are destitute of any organs, possess an epidermis with a double outline, and usually bear six, but in the *Tetrarhynchi* only four, very small microscopic hooklets on their anterior extremity, so that they carry their destination, that of boring forward through the tissues, as it were, written on their foreheads. The bodies of these small but very dangerous vesicles, whether armed or unarmed, are always capable of motion. The embryos which are destined to migrate into cold-blooded animals are much larger, possess larger hooks, and exhibit distinct movements in the usual temperature of a room. Those destined for warm-blooded animals are much smaller, with smaller hooklets, and exhibit distinct movements only about the temperature of the stomach. (KÜCH.)

38. iii. *The Destiny of the six-hooked Brood when set free.*—A. *What is the fate of this brood until it reaches its settled dwelling-place external to the intestinal canal?* As soon as the embryo becomes free in any part of the digestive canal of an animal which suits it, according to VAN BENEDEN, it brings together the central pair of its embryonal hooklets like a wedge, and at the same time, by thrusting and twisting, begins to force them forward. Having in this way made a little progress, it assists itself farther with the two lateral pairs of hooklets. KÜCHENMEISTER supposes that, having thus penetrated into the tissues, they pass into the blood-vessels, and thus they are conveyed either into the liver by the *vena portæ*, and remain fixed in the finest ramifications of the blood-vessels, or into the brain, or into other parts. The migration of the young of the *Cestoidæ* to the places where we meet with them as vesicular worms, or in analogous states, takes place in the following way:

39. 1st. A portion of the six-hooked brood, in all species of *Cestoidæ*, may reach their dwelling-place directly and by active migration, by boring their way. 2d Others, by an uncertain duration

of this migration, reach the vessels of the new host, penetrate these, and are conveyed with the blood to the smallest ramifications, where they (a) either become developed in these ramifications, the walls of the vessel becoming their envelopes; or (b) they migrate passively into the neighbouring tissues, after the rupture of the walls of the vessels, in consequence of the swelling of the embryo; or (c), after being detained in these ramifications, they enter anew upon an active migration, passing into the tissues by means of their hooklets, and increasing in size.

40. B. *What farther takes place with the embryos when they have come to rest in their new dwelling-places?* The third stage of the development of the *Cestoidæ* consists of the so-called vesicular worms and their analogous asexual forms, "which, in accordance with the alteration which the embryonal vesicle undergoes in the different species of tape-worms, and with the different animals infested by them, may be divided into *cysticercal* (vesicular worms), *platy-cercal* (forms with a flat, inarticulate, tail-like appendage), and *acercal* (or tailless) forms. It is a common peculiarity of all the three forms here mentioned, that they are cestode-heads produced from the embryonal vesicle, which occur still in a state of rest. We may therefore best comprehend this stage under the name of *resting scolices*." The metamorphosis or transition of the embryos to the resting, and usually *cysticercal* scolices, may be stated as follows:

41. 1st. "The embryo, still furnished with its six hooklets, begins to swell by the reception of fluid (liquid nourishment) which is secreted from the place in which it has established itself: this is at first a fluid similar to protoplasm, but after the formation of the enveloping cyst, or after the cessation of inflammation, when the creature lives free in the interior of serous cavities, it does not agree so much in its composition with the serum of the blood as with the ordinary products of the secretion of serous membranes." (LUSCHKA.)

42. 2d As soon as the embryo has in this way rather rapidly enlarged to a certain size, and arrived at a state of repose, the round vesicle thus formed, when it does not project freely into a serous cavity, and has not fallen into one, surrounds itself with an envelope, which protects it and assists it in procuring repose. These enveloping cysts constitute an absolutely new formation, which is analogous to serous membranes, and which constantly increases in size with the growth of the young cestode vesicle. When, however, the brood of a cestoid worm gets freely into serous cavities, it either never attains to this formation of an enveloping cyst, or does so at a rather late period, and at a time when the young embryo has become a vesicle of very considerable size, and often exhibits the *Tænia* head in an advanced state of development. In places where the young cystic worm again falls into repose, a fresh exudation of plastic matter adapted to the formation of cysts takes place, the walls of the cyst being rich in blood-vessels. (KÜCHEN.)

43. 3d. By the reception of the secretion of the serous membranes, the young cestoid vesicle swells up. At its anterior end, and at the point where the six embryonal hooklets are situate, a funnel-shaped pit is at first formed, and this gradually penetrates more deeply into the parenchyma of the embryonal body. In the bottom

of this pit the first traces of the head appear, while the lateral walls of the depression become converted into the body—the central body—of the future cystic worm, and the remaining portion of the embryonal vesicle, which is not inverted, or not implicated in the metamorphosis, becomes the so-called caudal vesicle. This inversion and first formation of the head most frequently commences at the anterior surface of the vesicle, and are seen distinctly in the cestodes of *Arion empiricorum*, for in these the six small hooks are placed in pairs at the point of transition of the central body into the caudal vesicle of the worm. The central body and the head are always developed in the interior of the embryonal vesicle, and during the whole period of the vesicular state the head always has its apex directed towards the caudal vesicle, even when the central body, which encloses the head in the form of a hollow canal, has not sufficient room in the embryonal vesicle, but is pushed out of it. (KÜCHEN.)

44. 4th. From the experiments of HAUBNER, KÜCHENMEISTER, LEUCKART, ROLL, VAN BENEDEK, ESCHRICHT, &c., with the various *Tania* which pass through a vesicular condition, the following appears: According to LEUCKART, at least in experiments with *T. serrata*, we find twenty-four hours after administration the six-hooked embryos in the blood of the large abdominal veins, especially the vena portæ; and on the fourth day, in the livers of rabbits to which they have been administered, small, white, clear vesicles of 0.3 millim. in diameter, but rapidly increasing in size, which on the sixth are already 1 mill. in diameter. In *T. serrata* the actual embryo, after the lapse of fourteen days, measures 1.5 millim.; in *Camurus* it is about the size of a grain of millet at this period. The small vesicle (the worm), after it has begun to grow clear, acquires, in its interior, numerous large, clear enucleate vesicles, which, according to LEUCKART, are similar to sarcode drops. In the parenchyma we recognise a cortical layer, which becomes thinner, and the cells of which are converted into muscular envelopes by fibre-formation, and a medullary layer, in which elastic vesicles or cells occur in great quantity. From the appearance of the medullary substance, the growth of the little worm, which is capable of motion even before the muscular layer is developed, advances with rapidity. Even in the first fortnight, and shortly afterward, the form of the young cestoid worm varies according to the species. Some, such as the younger *Camuri* and *Cystic. cellulosa*, *tenuicollis*, and *fasciolaris*, are spherical; others, such as *Cystic. pisiformis*, and probably also *Cystic. longicollis* and *fistularis*, are oval. Many of those seated upon the surface of organs, projecting into closed serous cavities, wander for a time in the organ, and finally fall into these cavities, the oval forms appearing to wander more than the round ones. About fourteen days after administration, the above changes take place almost universally and in all places. But those individuals which have not found a situation favourable to their development undergo a retrograde metamorphosis, passing "to the state of caseous, granular, or atheromatous masses, in which we may seek in vain for any remains of the embryo, although this certainly is present. Many cases of miliary tubercular disease of particular organs may indeed consist of nothing

else than the dead, fatty, and calcified young of worms."

45. 5th. In the third or fourth week, when the young brood of *Cysticercus pisiformis* measures about 2 millim., and that of the *Camurus* is of the size of a pin's head, we may see, according to LEUCKART, beneath the epidermis a layer of muscular fibres. Then follows a fatty structure, and then the medullary substance. At the point where the head is to be formed, a turbidity is produced by the aggregation of small nucleated cells, in the interstices between the muscular and medullary layers. This is the first foundation of the head of the tape-worm. Opposite to this turbidity a pit is observed externally, the inner wall of which is formed by the inverted epidermis, and which passes through nearly the whole depth of the globular foundation of the head; this latter appearing like a peg attached to the inner wall of the worm. In the central mass of the head, especially in its upper half, calcareous deposits appear, at first sparingly. Two or four vessels are also observed rising in a tortuous form through the upper part of the lobe, and passing over to the external sac-like envelopes. The vesicle now becomes larger and clearer, and the medullary layer, pushed against its peripheric layers, grows thicker, while vessels and calcareous corpuscles make their appearance, especially in the anterior part of the body, between the muscular and epidermic layers, but not in the former, in some cases before, in others after, the formation of the cephalic process. From the time when this process commences, the caudal vesicle ceases its activity in the true *Cysticerci*; its functions are then only passive, serving as a reservoir of nutriment, or as a protection to the head, which requires repose for its farther development, and preserving sufficient room for this end. I cannot follow the descriptions of KÜCHENMEISTER and other helminthologists farther, as respects the development of the head and its hooklets, &c., but must refer the reader to Dr. LANKESTER's translation of the work of the former, and to the other works referred to in the Bibliography. I may, however, notice the following conclusions of this observer:

46. 6th. In the progress of the metamorphosis of the six-hooked cestoid brood into scolices, it has been shown that a portion of the *Tania* pass through a true *cysticercal* (bladder-worm) state, while the other part, without ever arriving at this state, furnish exactly the same structure (cestoid heads—scolices). This latter part KÜCHENMEISTER has divided into *platycercal* and *acercal* forms.—(a) True *Cysticerci* occur only in warm-blooded animals, especially mammalia; and cysticercoid forms principally in cold-blooded animals.—(b) The eggs of all *Tania* which pass a cysticercal stage are distinguished by the small size of the embryo, and its six hooks, and by their brown, hard shell beset with asperities. The eggs of the *Tania* with only a cysticercoid phase of development have softer, colourless, transparent shells, are much larger, and contain a much larger embryo, furnished with larger hooks.—(c) *Tania* with a cysticercal phase of development are inferior to the platycercal and acercal forms in regard to the length and cylindrical form of the rostellum.—(d) *Tania* with a cysticercal stage possess during this a highly developed *receptaculum capitis*, which forms a part of the future neck, in which, as long as this stage lasts,

the head is introverted. The allied platycercal and acercal forms are destitute of the accumulation of fluid, and of the *receptaculum*.—(e) If the six-hook cestoid brood gets into animals which are not suitable to it, or into such organs in an animal otherwise suitable, it is destroyed in a very short time, even in the few first days of its immigration; the form of miliary tubercular disease of the organ may thus have frequently occurred. This may be demonstrated by administering mature proglottides to various animals.

—(f) A great number of the cestoid embryos which become developed to the scolex state die, and are destroyed either by a natural or a pathological death. We only know that their life may extend even to several years, but inflammatory processes and alterations of the secretions extending to them from the organs they inhabit may destroy them more or less rapidly, and change them into masses consisting of cholesterine, calcareous, fatty, suety, and similar substances.

47. iv. *The Scolex passing into activity*.—On this topic I must refer chiefly to recent writers, more especially to KÜCHENMEISTER, and notice merely a few of the more prominent parts of their descriptions. As a general proposition, it is inferred “that the animal infested by cystic worms is usually the source of food, or the prey, of that infested by tape-worms.” The host of the cystic worm is devoured by a carnivorous predaceous animal, and by this means the cystic worm arrives, together with his previous host, in the stomach of the carnivorous animal. During the process of digestion, the enveloping cysts in which the cystic worms were enclosed, or, if the animal lived free in cavities, these latter, perhaps both, are digested, or opened previously by the teeth of their devourer, when the cystic worm escapes into the cavity of the stomach. Here the worm extends itself; its caudal vesicle collapses. On the caudal vesicle and the middle of the body of the cystic worm digestion begins to act perceptibly. The body at the same time elongates and extends itself, but the head and the short neck are still inverted, as during the cysticercal state. But now the head and neck extend themselves. The head, the hooks still exhibiting the position of cysticercal existence, their apices being directed backward towards the suckers, and their shafts towards the apex of the head, draws itself, as it were, outward through the neck, by turning itself inside out. As a matter of course, the whole worm is thus turned inside out; and the margins of the head and neck which were previously turned in, become the free outer sides of the worm. A portion of the *receptaculum capitis* is then cast off, with the body and the caudal vesicle, and a portion wraps itself into the funnel-shaped constriction of the young *Tenia*.

48. At various times, sooner or later, according to the evolution and age of the cystic worm, the formation of segments commences, and with this, consequently, this stage of development is concluded. It should be recollected that *Tenia* cannot be reared from such scolices as do not exhibit perfectly-developed hooks. They die immediately. The first transformation of all cystic worms introduced into the intestines of a warm-blooded animal takes place in the same way; but the process stops before the commencement of segmentation, in those cases in which the intestine of the animal in which the vesicular worm

has arrived is unfavourable for it and its future development. Thus circumstanced, it lasts but for a short time, no trace of it remaining a fortnight after. The transformation of the platycercal forms into mature Cestoidea takes place exactly like that of the cysticercal forms; in the acercal forms no casting off of a portion of the former embryonal vesicle takes place, but the whole of it is retained, and the formation of segments commences immediately upon it. It still remains to consider—*How the scolex, after entering upon its activity becomes converted into a tape-worm colony—Strobila*.

49. v. *The Strobila, or the so-called Tape-worm Colony*.—“Immediately after the healing of the cicatrix on the neck and on the former *receptaculum capitis*, there commences between the posterior end of the head and this cicatrix a budding forth of the body, produced without sexual propagation, and which becomes constricted into segments by transverse furrows or wrinkles. By the constant production of new masses on this place, that previously formed is continually pushed farther back, so that this cicatrix is at last removed to a considerable distance (varying according to the species) from the head. During this time the individual segments increase, and grow in the same ratio as their removal from the head: they at the same time acquire sexual organs, male and female, in each segment, and which are very rarely, and probably never wanting in the colony. Finally, when they have attained a sufficient size and maturity, they produce the embryos (§ 41, 2), and last of all cast themselves free in the form of the proglottides (§ 36). If we were to give a definition of the strobila—it is a series of joints, or individuals, which are formed from the active scolex in the space between the part of the latter that must be called the head proper, and its cicatrized extremity, by a sexual reproduction; which are in direct union with the scolex, and which, when examined from the anterior to the posterior, present asexual segments, half and fully formed sexual segments, and segments engaged in sexual retrogression, the last of which have become truly independent individuals.” (KÜCHENMEISTER, *Op. cit.*, p. 84–5.) Thus we have seen how the segments with their ova and embryonic structures, are developed; and, when they have become the hindmost of the colony, cast themselves loose.

[Five different conditions, then, may be distinguished in the development and history of the *Tenia*: 1. *The embryo*, with six tenaculi; 2. *The Cysticercus*; 3. *The Scolex*; 4. *The jointed Tenia*; 5. *The independently living and sexually developed joint or section, proglottis*. The development of the cestodæ presents us therefore, as described by our author, a true instance of alternation of generation. Three different generations succeed each other in these animals: the embryo, with six tenaculi, as great-nurse; the scolex, as nurse; and the isolated living proglottis, as the generic animal. The great-nurse is the product of sexual development; she has her origin in the germinated ovum; while the two other generations are the products of budding or sprouting, the nurse from the grand-nurse; the generic animal from the nurse. The intermediate conditions of cysticercus and strobila must be characterized as polymorphous colonies. The strobila might be compared to a colony of polypi, in which each individual is growing out of the posterior body of the scolex, their native soil, thus forming

but one and a continuous line. Such a treble alternation of generation is also found in other animal organisms. It is to be understood that by the alternation of generation the generic animal produces *only* an unsexual race which is dissimilar to its parent, and remains so; and this generation produces, by budding, generations of new animals which, either themselves or their offspring, return to the original form of the stock.]

50. My limits admit not of a full description of the minute structure of the fully-developed *Tania*. It will be found in the work just quoted. I may, however, briefly state that no digestive apparatus has been found in these animals. Most writers assert that up to this time no nerves have been detected in them; but HUXLEY states that a single ganglion is situated in the axis of the head, and that it sends off nerves to the suckers in some *Tania*. The most important points are the dissemination of calcareous corpuscles in their structure, and the formation of circulating vessels. With the development of the scolex it was seen that a union of four principal lateral vessels takes place in the head, and that smaller branches are given off from these trunks. These vessels probably open outward near the *receptaculum capitis* or neck, or about the situation of segmental production; but the ultimate structure, connexion, and termination of these vessels have not been precisely determined. The muscles consist of transverse and longitudinal fibres, which may be recognised most readily in the neck. The suckers, peculiarly muscular parts, present radiate fibres uniting in the middle of the sucker, under which lies a layer of circular fibres, and the *rostellum*. It has not been ascertained whether or no muscular fibres run to the hooklets of the embryo. The hooks of the *Tania* appear to ride upon the skin or integument, or in slight impressions. The movements of the hooks seem to be produced by changes in parts of the head, particularly of the rostellum. The sexual organs, both male and female, exist in each segment, in which numerous eggs are produced. A very minute description of these organs—the penis, testes, vagina, uterus, &c.—is given by KÜCHENMEISTER.\*

\* The developmental history of the Cestoidea may be understood, if considered as follows:

"i. The mature sexual animal, which is produced by asexual gemmation, separates from the colony as soon as it has attained its majority, migrates actively from the intestinal canal of its host into free nature, and thence passively into the stomach of another usually herbivorous animal. It bears within it,

"ii. The grand-nurses or embryos produced by sexual, and perhaps by asexual, reproduction, furnished with four or six hooks, which are destined to enter passively into the stomach of an herbivore, and thence to migrate through the body of the latter, either actively, or by the intervention of the vessels, active—passive—actively. (The asexual propagation of the brood in the Cestoidea is rendered improbable even by the fact that, in the whole developmental series of these Cestoidea, a sexually mature animal has never been met with.)

"iii. The resting scolex (nurse), produced by asexual gemmation in and by the large six-hooked embryo, still concealed within this embryonal vesicle, or lying beside it enclosed in peculiar cysts, or in closed serous cavities. In its non-gemmiparous part the embryonal vesicle acquires, according to the species of cestoid worm, and according to the different hosts (cold or warm-blooded), sometimes the form of a globular vesicle, sometimes that of a flat band-like strip, and sometimes is only just sufficient to cover the scolex, lying quite close upon it, when it really forms nothing but a *receptaculum capitis*. Thus we obtain three forms allied to each other in their degree of development: the cysticercal forms (*Vermees cystici*, including *Cenuri* and *Echinococci*); the platyercal (similar to Stein's cestoid worm of *Tenebrio molitor*, and Von

51. THE CESTOIDEA, or Cestode worms, occur in man either in the mature state, and then in the intestines only (*Bothriocephalus latus*, *Tania mediocanellata*, *Tania nana*); or in the larva or scolex state (*Cysticercus visceralis* seu *tenacollis*, *Echinococcus veterinorum*, seu *scoliciparicus*, and *E. hominis* seu *altricparicus*); or, lastly, in all known stages of development (*Tania solium* and *Cysticercus cellulosa*).

52. Genus 1. BOTHRIOCEPHALUS = DIBOTHRIUM.—This division is abundantly represented in predaceous fishes, more sparingly in piscivorous birds, especially the marine Raptores, and rarely in a few mammalia. Of the terrestrial mammalia inhabiting inland places, man only harbours *Bothriocephali*. KÜCHENMEISTER defines this genus,\* and the species here to be considered, as subjoined,† and gives the following as the synonyms of the species, *Bothriocephalus latus* or *Dibothrium latum*; *Tania lata*, *T. grisea*, *T. vulgaris*, *T. membranacea*, *T. dentata*, *T. crinis*; *Ténie à amcaux courts*, *T. large*, *T. épinc*; *Lindworm*, *Baandworm*, *Bacndworm*: the tape-worm, jointed worm, the short-jointed worm.

53. i. GENERAL DESCRIPTION.—The colour of the living worm is bluish white. Specimens preserved in spirits change greatly in colour. The active scolex, or head, is obtusely conical. The two lateral pits (analogues of the sucking disks of *Tania*) are fissuriform, and appear, like the sucking disks on the feet of flies, rather to effect adhesion than to draw nourishment, which is probably introduced through the entire skin. The nec-

Sibold's from *Arion empiricorum*); and the acercal (contain embryos of *Tetrarhynchid*). Every one of these is a normal form; even the cysticercal forms are neither markedly degenerate, nor become dropsical, nor strayed.

"iv. The resting scolex, transferred into the intestine of an animal, becomes converted into the scolex *passive* into *active*. The latter is distinguished from the resting scolex by the extension of the entire body, by the altered position of the adherent apparatus (suckers and hooks), by the attachment in the intestinal canal, and by the cystical and platyercal forms, by the casting off of the barren portion of the embryonal vesicle, and the formation of a cicatrix on this spot. In the acercal form nothing is cast off, nor is there a cicatrix formation.

"v. The strobila—equal the tape-worm colony, budding immediately from the scolex, which has become active by asexual propagation (gemmation), is more or less distinctly jointed, and becomes sexually mature posteriorly. Its last segments, which are cast off, and lead an independent existence, are called *proglottides* (i.), and bear within them the embryos produced by sexual reproduction (ii.)." (KÜCHENMEISTER, *Transl.* by Dr. LANKESTER, p. 93.)

\* "Cestoidea, 2 oculis suctoriis, aut 2 foris marginalibus, oblongis aut longitudinalibus oppositis instructa. Capite subtriangulo, depresso, articulo plerumque inermi. Porci genitales omnium articulo in linea mediana animalis et in ejus superficie abdominali s. t. Scolices extra tubum intestinale in cystidibus peculiaribus ad verum platyercorum modum, aut in tubo intestinali animalium minorum aquaticorum statu immaturo viventes; Strobilae in tubo intestinali animalium aquaticorum rapacium, arum marinarum et mammalium viventes; Proglottides rere interdum absunt, interdum absunt, sepiissime in longa articulo serie conjuncte desinentes. Embryones sex hamulis armati; ovariorum testae sepiissime coloratae.

† "i. BOTHRIOCEPHALUS LATUS = DIBOTHRIUM LATUM.—Caput oblongum, inermis, 2 bothriis-foveis marginalibus, formam rimae aut fissurae (fente) adaptantibus; collum subnullum; articuli numero circa 2000, maturi omnino latiores (ad 27 millim.), quam longi, sociatim decedentes; porci genitales in linea mediana siti, masculus major et superior, ex quo penis laxis et brevis prominet, feminus minor, posterior inferiorque. Scolex quiescens ignotus; scolex activus cum strobila in hominis tubum intestinale incoens, longitudinem 7-8 unarum, secundum Dujardinum ad 20 metres (f.) exhibet.

"Embryones 6 uncinatis (f.) armati, in ovulis 0.025-32 mill. longis et 0.002 mill. lati, elliptici, flavo-fusci, operculo dehiscitibus inclusi."—KÜCHENMEISTER.

is more distinct in young than in old specimens, the transverse wrinkling, *i. e.* segmentation, commencing immediately behind the head. The *strobila*, or jointed body, presents a ventral surface, on which the sexual apparatus opens, the opposite being the dorsal surface. Each segment has four margins—two free lateral margins, slightly undulated, and an anterior and posterior margin, articulated with the upper and lower segments in the colony. The form varies according to the preponderating contraction of the longitudinal or transverse fibres, the breadth, however, being much greater than the length—as three to one. In the central line the segments are thicker (up to 1") and darker; the lateral margins flatter and whiter. The *vascular system* consists of lateral longitudinal cords, which contain a limpid fluid. A respiratory system and organs of sense are wanting. The *sexual organs* generally are single in each segment, but they are sometimes double.

54. *A. The Ova and Embryos.*—The former exhibit an external hard brittle shell, which often breaks so as to represent operculated ova, like those of the *Trematoda*. From the opercular opening a limpid vesicle emerges, in which, however, KÜCHENMEISTER did not find the six hooklets which VON SIEBOLD considers similar to those in the circlets of the *Tænia*. Possibly a part of the eggs of the *Bothriocephali* are not produced with undeveloped embryos, so that the latter are perfectly formed only when free in nature, as the eggs of the *Ascarides*. The resting scolex exists in the fishes, especially marine fishes. In these certain cestode worms live, having a band-like, inarticulate appendage, but exhibiting no commencement of sexual development. These become converted into mature *Bothriocephali* in the intestines of higher fishes, or of the marine birds of prey. Whether the cestode worms are developed in the intestines of fishes in which they are found, or are conveyed there in one or other of the animals on which these fishes feed, in which they had been converted into scolices, after the animal had swallowed the eggs of the mature *Bothriocephali*, is still undecided. Probably the ova and scolices are developed as already described (§ 37-47). As the host of the *Cysticercus* is devoured by an animal, in the intestine of which the scolex, being set free, immediately develops itself.

55. *B.* We have no data as to the production of the *Bothriocephalus latus* in man. This worm has been found in the cat, but is extremely rare in all terrestrial animals. The cat has evidently obtained it from the intestines of fishes, which in sea-ports and on the sea-coasts are left in large quantities, and are used as manures. It is difficult, notwithstanding, to account for the presence of this animal in man. The ova from the proglottides of this worm may, however, be introduced into the human intestines by means of vegetables, where the intestines of fish have been used as manures, or where they have been conveyed in sewerage water. The passive anigration of the embryo into the intestine of another animal, and its conversion in this intestine into an asexual band-like scolex, is much more probable than the development of all the grades in the same intestine, on account of the dissimilarity existing between the embryo and its parent.

56. *C. The physiological relations of Bothriocephalus* are chiefly its weaker vital manifesta-

tions, and the smaller number and less perfect development of its sucking organs, than those of the *Tænie*, which explain its easier expulsion from the intestines. The power of imbibing fluids by the bodies of the *Bothriocephali*, and all *Cestoidæ*, has been proved by ESCHRIENT and others. Transudation takes place in small, pellucid, oleaginous drops (sarcode). While the *Nematoda* and *Echinorhynchi* swell up by imbibition, the *Cestoidæ*, owing to an abundant exudation, experience only a slight swelling from imbibition. Whole series of segments of the *Bothriocephali* pass off spontaneously, but never single segments, as in the *Tænie*. The duration of the life of the former is not known. More than one or two worms of this genus are rarely found in the same intestine, and their length seldom exceeds twenty feet.

57. Genus 2. TÆNIA.\*—i. TÆNIA SOLIUM, and its *Scolex-nurse*=*Cysticercus cellulosus*.

SYNONYMES.—*Tænia*, Aristotle; *παραία ἐλμυς*, Hippocrates; *Lunbricus latus*, Pliny; *Tænia solium*, Linnæus et Auct. permulti; *T. cucurbitina*, Pallas, Goeze, &c.; *T. vulgaris*, Wer-

\* "Second Order (KÜCHENMEISTER), TÆNIE.—*Cognat subglobosum aut tetragonum; acetalibus oculis surtorius 4, rarisime 6, muscularibus, orbicularibus, symmetrice oppositis, valde contractilibus; rostellum imperforat, retractile, in scolicebus quiescentibus inverso, in a tiris s. Tæniis maturis propulso, hamulorum simplicium, duplicit, aut multiplicit corona armato; corpore plerumque albo, plano, depresso, bilaterale aut triquetro, articulo (Strobila); articulis maturis androgynis, aut non asexualibus (2), sponte et alio post alium dehiscens, Trematode nudam similibus (Proglottides); systemate ruscioso perclaro; poris genitalibus lateralibus, plerumque alternantibus, masculo majore et anteriore, femine minore et posteriore; genitalibus perfectis. Scolices quiescentes et immaturi formam cysti-, pluri-, aut necerum ineuntes. Scolices activi cum strobila longitudine et latitudine valde variantes. Embryones 6 hamuliculis armati, parvuli, periceves; ovula in illis qui formam cysticercum ineunt, minima, pileata, flavescentia, in ceteris majora, leviora et clariora."*

1. TÆNIE WHICH OCCUR IN MAN IN THE MATURE STATE.—i. "Tænia solium, and its scolex nurse= *Cysticercus cellulosus*.—Tænia matura = *Scolex activus cum strobila*: longit. 4-5 metres = 6-8 unguarum, latit. ad 13 millim. Caput = scolex sensu striatore, brevis, antorsum planum, 0.56-0.95-1.0 mill. lat., acetalibus validis, prominens, 0.12-0.21" = 0.434-0.521 mill. long., et 0.132-0.224" = 0.410-0.505 mill. lat.; rostellum parvulo 0.4 mill. ad latera nigrescente; hamulorum 22, 24, 28, 30, plerumque 26, duplice ordine, longit. 0.167 quoad majores, 0.11 mill., quoad minores hamulos (secund. LEUCKART), 0.13 et 0.12 secund. meas mensuras, ungue et stylo hamulorum ex longit. fere similibus, formâ hamulorum omnino eadê; locis hamulorum perclaris, nigrescentibus; collo parvulo, fere nullo; corpore antorsum maxime attenuato, deorsum ad 10-14 mill. lato, articulo, poris genitalibus alternantibus, interdum irregulariter; utro ramis 6-10-13, irregulariter alternantibus, demum ramificatis instructo; corporibus calcareis in capite rarioribus (0.004" = 0.009 mill. long. et lat.), in corpore crebrioribus et majoribus (0.005" = 0.012 mill.). Proglottides ad 16 mill. longæ et ad 6 later, ad inferiorem partem crassiores, margine magis toroso et angulis magis prominentibus, quam ad superiorem partem, ut in aliis Tæniis, oculis 0.016" = 0.036 mill. long., 0.016" = 0.035 mill. lat.; testâ ovariorum crassiore (0.0063 mill.). Embryonibus 6 hamulis ornatis, 0.023-0.032 mill. long. et lat., migratione indigentibus.

"Habitat.—Solitarie aut solaliter (ad 40 usque) in tubo intestinali hominis, inque terris diversissimis; vix in Canis domestico.

"Scolix quiescens = *Cysticercus cellulosus*, vesicâ cuticuli haud magnâ (ubi plurimum 15 mill. in diametro) transverse ellipticâ; corpore inverso, transverse rugato, 8-10 mill. longo. In tubum intestinale translatum intra 3 menses maturarescit. Habitat in telâ cellulosa totius corporis et nonnullis corporis cavitatibus clausis (oculis, cerebro, &c.) imprimis in homine, Sic scrasâ comesticia, rarius ferâ, Simiâ, Cerco, Capreolo, Cane domesticio (Arachnoidi, et mus ul.) valde dubiosis in primone Cimis domesticis et Muris Ratti. Per injuriâ a nonnullis Cæburis cerebriâ hominis nominatus."—KÜCHENMEISTER.

ner; *T. dentata*, Gmelin, Nicolai; *T. osculis marginalibus solitariis*, Bradley; *T. armata humana*, Brera; *T. lata*, Reinlein; *T. fenestrata*, Delle Chiaje; *T. stigmatibus lateralibus*, Bonnet; *T. secunda*, Plater; *T. solitaria*, Leske; *T. articulos demittens*, Dionis; *Halysis solium*, Zeder; *Pentastoma coarctata*, Virey; *Vermiscucurbitinus*, Plater; Kürbiswurm, Kürbisformiger; bewaffneter Bandewurm; Kettenwurm, Germ. Ténie à longs anneaux; T. sans épines; T. de la seconde espèce; le solitaire; ver solitaire; T. bandelette, &c. The following names are also given it, in common with *Bothriocephalus latus* and *Tania medrocanellata*: le ver plat, Bandelorm, tape-worm, jointed worm.

58. *Tania solium* presents five steps of development. 1st. The sexual animal—*Proglottis*; 2d. The grand-nurse—six-hooked embryo; 3d. The resting *Scolex*—*Cysticercus cellulosus*, in the parenchyma, areolar tissue, and cavities of the body; 4th. The active *Scolex*-nurse, that is the *Cysticercus cellulosus*, which will become a *Tania solium* in the intestines; and, 5th, the *Strobila*, the series of segments of *Tania solium* produced by gemination from the fourth step.

59. A. THE MATURE *TANIA*.—The name *Tania solium* is incorrectly applied to this worm, inasmuch as frequently two or three occur in the same person. Dr. PFAFF has seen seven expelled, KÜCHENMEISTER ten, HELLER thirty, and KLEEFELD counted forty expelled from one patient.

60. (a) *The Strobila*.—The head, although varying somewhat in size, is seldom larger than the head of a common pin. It is of a blackish-brown colour, especially around the base of the short rostellum, and in the sacs around the base of the hooks, and in and around the sucking disks. The hook-sacs, as well as the hooks, are placed in a double circular series. The one series does not materially differ from the other. As in all the *Tania*, the points and spines of all the hooks fall in the same circle, or in two circles lying close together, the number and position of the hooks corresponding with the sacs, and varying from 22 to 28. The sucking disks are nearly circular, or somewhat oval, and surrounded by a circular collateral branch of the longitudinal canals, by which a sort of vascular net is formed. Close behind the sucking disks, and near the head, the vessels collect in four main branches, which are united quite at the front of the head by a common transverse branch, thicker than they. In the vessels of various *Cestoides*, VIRCHOW, WAGENER, and others, have seen a sort of ciliary epithelium projecting into them, and moving in the fluid. The calcareous corpuscles reach about to the middle of the sucking disks. They are few and small on the head. The slender neck, of about 6" in length, exhibits no traces of transverse striæ or segmentation. The calcareous corpuscles are somewhat more abundant, and also larger than in the head. Behind the neck commences the true jointed body of the *Tania*, in which KÜCHENMEISTER counted 825 segments in one specimen ten feet two inches in length. The proportionate size of the segments gradually increases posteriorly, or as they depart from the head—in length from 1.12" to 7". In this species, as in all *Cestoides*, contact with water causes the emission of DUJARDIN'S sarcodæ, in oleaginous drops. The sexual organs appear from about the 280th to the 300th segment, and onward, from the

head, in the median line of the *Cestoides*, at first as a simple brownish-yellow canal, with short lateral offshoots, towards which two transverse slightly coloured lines (seminal cord and vagina) run from the sides. The alternating *pori genitalis* first appear about the 317th segment, and become distinct in the 350th. The sexual organs are more and more developed from the 350th to the 600th segment, where ova commence, which become mature from the 650th to the 700th segments. Both male and female organs generally exist in the same segment, and are minutely described by KÜCHENMEISTER. Each joint, when divided, presents, 1st. *Epidermis* of a chitinous structure, without calcareous corpuscles; 2d. *Longitudinal fibres*, with calcareous corpuscles; 3d. *Transverse fibres*, with few calcareous corpuscles; 4th. Sexual organs.

61. B. *SCOLEX OF TANIA SOLIUM*.—*Cysticercus cellulosus*.—The former is identical with the latter as proved by the identity of the head in both; by the general and particular circumstances under which *T. solium* occurs, and by converting, by experiments in feeding, *Cysticercus cellulosus* into *Tania solium*, and the eggs of the latter into *Cysticercus cellulosus*.

62. (a) *The ordinary habitation of the Cysticercus cellulosus* is the flesh of the pig; and *Tania solium* is almost entirely unknown where the use of this flesh is avoided, as among the Jews and Mohammedans, who strictly adhere to their religious precepts. On the other hand, *Tania solium* is abundant wherever the breeding of pigs occurs, as in Poland, Hungary, Pomerania, Thuringia, England, &c., "and especially among those engaged in trades which bring them in contact with raw pork, and therefore with raw *Cysticerci*, as butchers, cooks, sausage-makers." KÜCHENMEISTER found *Cysticerci* in the water used in washing sausages. The direct proof of the identity of this cystic worm and *Tania solium* is shown by the following experiment upon a murderer condemned to death. Exactly 72, 60, 36, 24, and 12 hours before his execution, 12, 18, 15, 12, and 18 specimens of *Cysticercus cellulosus* were administered to him partly in rice or vermicelli soup of a blood heat, and partly in blood-puddings. The *Cysticerci* had already lain seventy-two hours in a cellar before KÜCHENMEISTER discovered them. The last administered had consequently lain about 130 hours out of the living organism, and he hardly believes that those *Cysticerci*, which had lain more than eighty hours, were still capable of development, any more than he can believe this to be the case with the *Cysticerci* contained in smoked sausages and hams. On dissection forty-eight hours after execution, he found ten young *Tania*, of which six were deprived of their hooks, but four distinctly showed the hooks of *T. solium*. The little *Tania* were 4 to 8 millim. in length, and had attached themselves by their hooks and proboscis to the intestine, and possessed a small band-like appendage, 2 to 5 millim. long. The preceding experiment is proof of the conversion of the cystic worms into *Tania* in the human intestine, and also of the mode of infection. KÜCHENMEISTER is convinced that the scolex of a *Tania* retains its power of development in its dead host only as long as no putridity occurs.

63. (b) The farther proof of the identity of *T. solium* and *Cysticercus cellulosus* is derived from the structure of the head of the latter. "This

cystic worm, like all others, forms a vesicle the size of a pea or very small bean, with a little white head in its interior, from which the true scolex may be evolved by pressure. This scolex bears a head with four, and sometimes six, sucking disks (the latter especially in the human brain), round which the vascular system runs, and collects into two longitudinal canals on each side. The short rostellum bears from twenty-two to twenty-eight hooks, placed in a double crown. Besides these, the head exhibits a sparing brownish-yellow, or blackish-brown pigment,\* and five sacs round the stems of the hooks. The neck is very short, poor in calcareous corpuscles, opaque, and colourless; the body is wrinkled, abounds with calcareous corpuscles, and the head is inverted into it as long as the caudal vesicle is alive and uninjured. After the death of the worm the head becomes everted. (See also § 46, *et seq.*)

64. (c) *Proofs of the Conversion of the six-hooked Embryos enclosed in the Eggs of Tenia solium into Cysticercus cellulosæ*.—KÜCHENMEISTER, in 1851, expressed the opinion that the pig infects itself with *Cysticercus cellulosæ* when it meets with the eggs and proglottides of *Tenia solium* upon the pastures; and in 1853 VAN BENEDEN administered *T. solium* to two pigs, and thereby rendered one pig measly. The following year KÜCHENMEISTER fed three sucking-pigs, on the 7th, 24th, and 26th of June and 2d of July, with segments of tape-worms, partly given off spontaneously and partly artificially expelled. On the 13th of July they were again fed with artificially expelled segments. "One of the pigs was killed on the 26th of July, and exhibited young *Cysticerci* corresponding with the days of administration, of which the largest individuals formed vesicles of the size of a hemp-seed, with a central turbidity, *i. e.*, the commencement of the head. The second pig was killed on the 9th of August, when thousands of *Cysticerci* were found in all parts of the body; the largest individuals were as large as peas, and exhibited a distinct head, while the smallest were only of the size of a hemp-seed. The third pig, which was killed on the 23d of August, was uniformly set, throughout all parts of the body, with *Cysticerci* of various degrees of growth and development. The largest were almost perfectly developed; others resembled those last described. He undertook the examination of a weighed piece of the flesh, and found 133 *Cysticerci cellulosæ* in  $4\frac{1}{2}$  drachms of it. If we calculate from this quantity the number of *Cysticerci* which would have existed in 1 stone, or one fifth cwt. of the pork, we obtain the great number of 88,000 individuals in this weight. A fourth pig of the same litter, to whom no *Tenia* had been administered, exhibited no traces of *Cysticerci* on dissection." (KÜCHENMEISTER, *Op. cit.*, 121, 21.)

65. LEUCKART repeated and confirmed the above experiment, and recognised, in the mode in which *Cysticercus cellulosæ* is developed from the embryo of *T. solium*, exactly the same type as that above described as the type of the formation of the so-called *Cysticerci* in general. It may, however, be noted that this worm acquires the vesicular form, and becomes covered with a vascular net, rather early, and at a time when no trace of the head can be observed. The first appearance of the head commences in *Cyst. cellulosæ* soon after the seventh week, at which time the embryo is about 2.5 millim. in diameter.

66. (d) *The Scolex of Tenia solium, Cysticerc-*

*cus cellulosæ*, has hitherto been found in the most various muscles; in the muscles of the heart, in the cellular tissue, in the brain, and in the eye of man. In these it acquires various forms and sizes, according to the space afforded for its development. In the ventricles of the brain and eye, its caudal vesicle attains even the size of a walnut, and remarkable forms. The size and form of the *Cysticercus* are determined chiefly by excess of nourishment, and by softness, looseness, and other properties of the tissues in which it occurs. The form is not material, the nature of the worm is the same.

67. (e) *The symptoms it produces differ with its seat or position.* It is almost harmless in the sub-cutaneous cellular tissue. In muscles it often occasions but little inconvenience. In the muscles of the heart, however, it may cause softening and other organic lesions. But its situation in the deeper muscles, even in the muscles of the heart, admits not of diagnosis. The situation of this *Cysticercus* in the eye is very important.—a. It has been found between the conjunctiva and the sclerotica, where it is of least serious occurrence, as it may easily be removed by operation, as in cases recorded by HÖRING, ESTLIN, BAUM, and others.—b. In the anterior chamber. It was first seen in the living subject by SOEMMERING and SCHOTT, and in the posterior chamber by VON GRAEFE.—c. In the vitreous humour by the last-named writer and others.—d. In the retina and under the retina in very rare cases. In these latter situations this cystic worm has been detected during life chiefly by means of the ocular speculum of HELMHOLTZ. In most of these cases, partial or complete loss of sight by the affected eye, squinting, movements of the worm, inflammation of the structures, followed by partial disorganization, and a greenish tint of the vitreous humour, were the symptoms chiefly observed. In rare instances only were tape-worms present, or *Cysticercus* present in other parts of the body.—e. *Cysticercus cellulosæ* in the human brain seldom occurs, and as seldom can be recognised during life, unless conjoined with cerebral symptoms, vertigo, &c.—f. *Cysticerci* are observed in other parts of the body, or *Tenia solium* has existed at an earlier period of the life of the patient.

68. ii. *TENIA MEDIOCANELLATA\** (KÜCHENMEISTER).—DESCRIPTION. (a) The epidermis of the animal is distinct, soft, consisting of delicate decussating lines, without calcareous cor-

\* "*Tenia matura*.—Species longissima (ad 12—14 *ulnas* longa), latissima, crassissima. Capite therni, permagno, ad 2 millim. lat., valde nigrescente; acetalibus 4 permagis (ad 0.367" = 0.829 millim. long. et 0.259" = 0.711 millim. usque lat.).

"Systemate vasculoso: in capite simpliciore, quam in *T. solium*; Corpore calcar.: ad 0.012 millim. in capite, ad 0.018 millim. in articulis magnis, magisque numerosis, quam in *T. solium*. Rostellum nullum. Collum perbreve, sed distinctius, quam in *T. solium*. Articuli posteriores latissimi, ad 17 millim. lat. et ad 9—14 millim. long. crassius; poris genitalibus irregulariter alternantibus. Proglottides permagis et pervicaces, scississime sponte et sine fecibus humanis ex ano demissa, apertumque valde perturbantes; in maxima sua extensione 25—30 millim. long. et ad 7 millim. lat.

"Uterus permultos ramos (ex utroque latere usque ad 30) in margine libero claviformes, non amplius dendritice, ad summum bifurcatum divisos, inter se parallelas. Ova magna ovalia, leviora, et clariora, quam in *T. solium*, ad 0.036 millim. longa et 0.028—33 lata. Testa crassa uti in *T. solium*. Embryones 0.028—32 millim. longi, 0.023—26 lati.

"Scolex quiescens ignotus. Fortasse in sue aut bore, fortasse in animal. inferior. ordinum."—KÜCHENMEISTER.

puscles. Underneath are longitudinal fibres, running through the whole body of the animal; these, as well as the next layer of transverse fibres, contain the calcareous corpuscles embedded in them. The size of the sucking disks, which are quite black, gives the head of this *Tænia* a considerable bulk. Transverse vessels run through the space between the sucking disks, and from these a branch runs to and around the disks, until the four longitudinal vessels are developed from them in the neck; these vessels becoming thicker as the segments increase in size. The segments, which have a great tendency to increase in breadth, are at first 1 millim. in length, and about three in breadth. Afterward, also, the breadth predominates over the length for a considerable space. But this proportion does not continue downward, and segments of 1—1½ in. of length and only 3—4 lines in breadth are met with. That the last segments or proglottides have a tendency to pass away without faeces is beyond a doubt; but this also takes place with *T. solium*, although more rarely. The segments usually pass when the patient is standing, and passing along the thighs, occasion a moist and cool sensation, and are found creeping over the surface.

69. (b) This *Tænia*, when artificially expelled, breaks off close to the neck. After the lapse of about ten weeks from this expulsion, a fresh passage of proglottides takes place. From the spontaneous passage of these without faeces it may be inferred that the reproduction and growth of the segments are extremely rapid, and that the animal must be more injurious to its host than *T. solium*. KÜCHENMEISTER mentions a case in which the number of proglottides, which passed almost daily, amounted, in the aggregate, to upward of 100 feet in 80 days; and that in the course of this time 1½ foot of tape-worm was passed and regenerated each day. The internal irritation of the rectum and anus, produced by these segments when forcing their passage, and the unpleasant clamminess they occasion, especially by the deposition of their eggs, which often also occurs at this time, and which appear like to a white moist sand, are very distressing to the patient. In the case just referred to, from 5—15 proglottides passed daily from the patient with the faeces; and as these immediately laid their eggs, the faeces looked as if sprinkled with white sand.

70. (c) The *Scolex* is unknown. In Dresden it cannot be rare, as this *Tænia* is not uncommon there. It is not improbable that the cystic worm belonging to this species may occasionally occur among the specimens pronounced to be *Cysticercus cellulosa*. This point might have been determined by feeding pigs with the eggs of the *Tænia*. An intelligent patient, from whom KÜCHENMEISTER expelled this *Tænia* by means of his preparation of the extract of pomegranate root, states that he had observed his *tænia* soon after dining frequently, at an eating-house, on raw beef-steaks and green salad and radishes. The scolex was either seated in the beef, or in molusca in the salad or on the radishes. "The embryos resemble in size and structure those of *T. solium*. Their migrations are unknown." Its habitat appears to be in Europe and Africa.

71. VARIETY\* from the Cape of Good Hope.—

\* "Nihil notum, nisi Strobile pars posterior. Articuli per totum corpus, cristâ longitudinali præditi, crassi, et longi. Pori genitales marginales alternantes. Uterus et

A number of segments of this *Tænia* were expelled by pomegranate bark, and, like *T. mediocanellata*, were very difficult of expulsion. They were destitute of head and neck. Its total length must be at least 6—10 yards. Its segments are very thick, white, and fat; in the mature state more than one inch in length, and 3—5" in breadth, and extremely massive. They are distinguished by having a longitudinal ridge along the whole of the mature and immature segments. This *Tænia* is rich in cholesterine. Mr. ROSE, who sent the segments to KÜCHENMEISTER, states that the migrations of the six-hooked embryos and the scolices are unknown, that it is impossible that the latter should live in the flesh of pigs, as the worm was obtained from a Hottentot, and the Hottentots, like the Jews and Mohammedans, eat no pork. A thick *Tænia* occurs in Abyssinia, among Mohammedan inhabitants. The Hottentots probably brought this tape-worm with them from the Caffre wars, in which they enjoyed themselves among the cattle of the Caffres. The scolex probably lives in their cattle and sheep. May not the scolex have been a *Cysticercus tenuicollis*?

72. iii. *TÆNIA NANA*† (BILHARZ; VON SEBOLD).—This small filiform *Tænia* has broad and perfectly developed segments, and a large quadrangular head, at the angles of which the round sucking disks are placed upon globular eleva-

ovula simillima illis *Tænie* mediocanellatæ. Verum, ut limum est, strobilum nihil notum proliferatum esse. *Tænia* mediocanellatæ scolice quodam 6 oculis ornato. —KÜCHENMEISTER.

\* [In a recent work by Mr. PARKYNS, entitled "Life in Abyssinia" (New York, 1845, 2 vols.), we find it stated that the whole population in Abyssinia are affected with tape-worm; that out of above forty persons, male and female, employed by the writer as servants only two were exempt from it. It is in that country ascribed generally to eating raw meat, which is a universal custom. Mr. P. states that the Abyssinians are in the habit of taking physic regularly once every two months to relieve themselves of the malady; that they also use the *kayapo*, both the flowers and seed, besides the bark of another tree whose botanical name is not given; although the *kayapo* is always preferred, when it can be had. The dried flowers are ground or powdered as fine as possible, and a strong infusion made, of which the patient drinks half a pint, fasting: about six hours after, a good quantity of beer is drunk. Mr. PARKYNS supposes, as many white persons who visit the country are infected with *tænia* who do not eat raw meat, that the cause is to be sought for in the climate or in the use of bread made of a species of millet. Vol. ii., p. 224, 5. KÜCHENMEISTER, however, has proved by his experiments that individuals fed on pork tainted with measles, and containing the cysticercus, become subject to tape-worm. Various German writers have supposed that these entozoa are destroyed by boiling, salting, and smoking the pork. Dr. RIECKE, of Nordhausen, has published a paper in which he recommends the prohibition of the sale of pork unless it has undergone these processes; and, in support of these views, he states that *tænia* is an exceedingly frequent complaint in the neighbourhood of Nordhausen, where there is a large consumption of raw pork by the people; and, on the other hand, that at Altmärk, where this practice is not prevalent, he has only seen six cases of this disease among about ten thousand patients who have been under his care during a period of fourteen years.—*Ed. Med. Jour.*, Dec., 1850, p. 560. Also, for June, 1855. The same subject, the production of *tænia* by eating raw pork, is also ably treated by Professor ALLEN THOMPSON, in *Glasgow Journal*, July, 13, 1855. Professor BENNETT entertains doubts whether the salting of pork is capable of destroying the vitality of the cysticercus.—*Ed. Med. Jour.*, Feb. 18, 1855. See, also, HENKE'S *Zeitschrift*, 3, 1855.]

† "Corpus filiforme, depressum; Caput antice obtusum, collum versus sensim attenuatum, acetabulis subglobosis, rostellis pyriformi uncinulorum bifidorum corona armatum. Articuli transversi; cirri unilaterales, ovula globosa; testa levi simpliciter (C) instructa 1-100" magni. Longitudo totalis 6-10". Patria Egyptus, in hominibus intestino tenui semel reperta numero permagno." —KÜCHENMEISTER.

tions. The head is flat in front, and gradually diminishes in breadth, and passes into a long slender neck, which is followed by segments which become broader, until at last the hinder segments are three or four times the width of the head. These *Tæniæ* occupy only a limited space of the ilium. The ova are globular. The six hooklets of the embryo *Tæniæ* are distinctly seen in the fresh ova. From the number of the *Tæniæ* found, and their very small size, KÜCHENMEISTER has believed this worm to be a *Tænia echinococcus*.

73. iv. SYMPTOMS AND DIAGNOSIS OF THE MATURE CESTOIDEA OCCURRING IN THE HUMAN INTESTINE, OF BOTH BOTHRIOCEPHALI AND TÆNIÆ.—KÜCHENMEISTER remarks that the stronger the patient is, the less the irritability of his system, the more regular his appetite and food, the fuller and richer his nourishment, the fresher his colour, the less he is inclined to diarrhoea, to anæmia, and chlorotic symptoms, the less does he complain of tape-worm. According to most writers, chlorotic or anæmic symptoms are increased by the great appetite of the tape-worm for proteinic substances, calcareous salts, and fat; and according to the degree of the symptoms are also the complaints of the patient. SEEGER gives the following statement of the frequency of particular symptoms in 100 cases of tape-worm: In 68 instances nervous affections and general or partial convulsions occurred—epilepsy, hysteria, abdominal spasms, convulsive cough, dyspnoea, melancholy, and hypochondriasis. In 49 cases nausea, with faintness and vomitings, was present; in 42, various pains in the abdomen; in 33, disordered digestion and irregular states of the evacuations; in 31, irregular appetite and voracity; in 19, habitual or periodical hemiparesis; in 17, sudden colic; in 16, sensations of undulatory movements in the abdomen up to the chest; in 15, vertigo, delusions of the senses and defects of speech; and in 11, shifting pains in various parts. These symptoms are deceptive; many of them will be often experienced after the worm has been completely expelled; and even viewed in connexion with the patient's habits, occupations, and residence in a locality in which the *Cestoidæ* are known to be prevalent, are not of themselves diagnostic of the existence of tape-worm. It is only by the discharge of segments of the worm that the nature of the disease can be satisfactorily recognised. The passage of the segments *per anum*, either with the fæces, especially when there is diarrhoea, or without this accompaniment, is the most frequent. The discharge of them by the mouth is extremely rare, and can occur only when there is violent vomiting, and when there is dangerous obstruction of the bowels. The passage of them through the intestines into the peritoneal cavity, or into the urinary bladder, or through fistulæ opening on the surface of the body, can occur only when ulceration of the intestines has been followed by perforation and a fistulous communication in either of these directions, or after wounds penetrating into the bowels. These several ways by which segments of tape-worm were passed externally were known to the older writers, and were ascribed by them to the mechanical or perforating action of the worm. But it is singular that, whenever ulceration and perforation of the bowels occur coincidently with the presence of worms, an instinctive desire of the latter to es-

cape from the bowel, through either the morbid opening or the natural passages, is observed.

74. v. IMMATURE TÆNIÆ FOUND IN THE HUMAN BODY EXTERNALLY TO, BUT NOT WITHIN, THE INTESTINES.—These form the CYSTICI and ACEPHALOCYSTIDES of older writers. The CYSTICERCUS CELLULOSÆ, being identical with *Tænia solium*, has been noticed when treating of that tape-worm (§ 62, *et seq.*). I shall only briefly notice the other immature *Tæniæ* occasionally found in the human body externally to the intestines.

75. A. CYSTICERCUS TENUICOLLIS (ESCHRICHT), CYSTICERCUS VISCERALIS (AUCT.).—As the mature *Tænia* of this cystic worm is not found in man, but chiefly in the dog and wolf (*Tænia marginalis*), I shall not occupy any part of my limited space by describing it, but refer the reader to Dr. LANKESTER's translation of KÜCHENMEISTER's work (p. 178).

76. (a) The *Scolex* or immature state\* of this *Tænia*, however, being sometimes formed in man, especially in former times, requires a brief notice at this place: it forms the *Cysticercus tenuicollis* of recent writers, and the *C. visceralis hominis* of earlier authors. The rarity of this scolex in human subjects in modern times has induced VIRCHOW and DIESING to doubt its occurrence, while ESCHRICHT has proved its rare appearance in man, especially in the liver.

77. (b) The structure of this cystic worm is rendered remarkable by its frequently enormous caudal vesicle, which in animals may attain the size of a child's head, by the concentric wrinkles or rings, visible externally, which pass round the worm, and which are crossed by very fine longitudinal striæ, so that when it is laid upon a plate, and held on the same plane with the eye, the animal has a finely checkered appearance. In the dead *Cysticercus tenuicollis*, incrustated with calcareous matter, these concentric rings may be recognised, and the calcareous deposit often forms a plastic-like cast of the form and structure of the cystic worm. The parietes, also, when a transverse section of the dead *Cysticercus* is made, present a structure consisting of concentric strata, analogous to that of the *Echinococci*. Here, however, it is so extremely fine and delicate, that there is great trouble in detecting it.

78. B. ECHINOCOCCI.—Some naturalists admit only of one species or variety of *Echinococcus*, others of two, and others of even a greater number. VON SIEBOLD divides this species into *E. hominis* and *E. vcterinorum*; but, from the accounts of various writers, both varieties have been found in the human subject.

79. 1st Var. ECHINOCOCCUS SCOLICIPARIENS†—*Echinococcus vcterinorum*, of authors.

\* "*Scolex quiescens*—*Cysticereus tenuicollis*. Vesicæ caudali tenui permagna (1, 2, 4, 6" et ultra); Corpore 14—30 millim. et ultra longo, 5—10 millim. lato, cylindrico; Collo 8—15 millim. longo; Capite uti in *Tænia filis* 2 gelatinosis, pone collo ex receptaculo capitis aut scolici in vesicæ cavitate emissis. Metamorphosis in *Tæniam* 10—12 hebdomadis post partum peracta.

Habitat. Rarius in hominis abdomine (mesenterio et hepate), sæpius in Ruminantium, Equi, Suis Scrofæ Scuri, Simie, &c., cavitate abdominali."—KÜCHENMEISTER.

SYNON.—*Tania visceralis granulosa*, GÖZE; *T. granulosa*, GMELIN; *Vesicaria granulosa*, SCHRANK; *Hydatis erraticia*, BLUMENBACH; *Polycephalus hominis*, GÖZE; *Pol. granulatus*, ZEDER; *Pol. Echinococcus*, ZEDER; *Echinococcus velerorum*, RUDOLPHI; *Echin. giraffe*, GERVAIS; *Echin. simiae*, RUDOLPHI, alique; *Echin. granulatus*, RUDOLPHI; *Echin. infusorius*, LEUCKART; *Echin. polymorphus*, DIESING; *Echin. scolicipariens*, KÜCHENMEISTER.

80. (a) The mature *Tania* has hitherto not been found in the human subject. VON SIEBOLD in 1852, and KÜCHENMEISTER in 1854, bred this *Tania* by giving *Echinococci* to dogs. The description in the subjoined definition gives all that is required to be known of it; but the eggs and six-hooked embryos must occur at some period in the human intestines, in the water and raw articles of diet, especially vegetables, fruits, roots, &c. Like the embryos of other *Tania*, however, they escape the human eye. "Their migration is certainly performed, like that of the embryos of other *Tania*, by their perforating the intestine and getting into the abdominal cavity, where they prefer attaching themselves to the liver or the kidneys, or to the organs in the thoracic cavity. A portion of them, however, may migrate along the *ductus choledochus* to the outer surface of the liver." They take up their position in the same way as the other *Cestodea*, the envelopes formed around them being similar, but much thicker.

81. (b) The *Scolex* forms a vesicle which, according to ESCHRICHT, measures  $2\frac{1}{2}$  to 3 inches, and is firmly attached to the organ in which it dwells. The enveloping cyst is like others, but more concealed and more abundantly permeated by proteinous unorganized substances, by which its walls are thickened. It may be partly separated into layers, the inner being smooth, like a serous surface. A second vesicular body fits exactly to the inner surface of the innermost layer of this enveloping cyst, and is the true *cystic worm*, the so-called mother vesicle of the *Echinococci*, that is, the six-hooked embryo, which, continually increasing, has attained an extraordinary size. It is almost impossible to get the cystic worm uninjured out of its cyst, to which it adheres so firmly. The walls of this worm are elastic, and tremble like jelly, when touched, even after they are empty. They never collapse altogether as seen in *Cysticerci*, nor lie, like these, even when dead, at the bottom of the envelope cyst. Their cut margins roll themselves up, and present a gaping appearance. The transverse section of this cystic worm shows a structure of more or less numerous consecutive circular strata, varying according to age.

82. c. The structure of this cestode has been described by ESCHRICHT, VON SIEBOLD, and others,

instructa; Oculis ovalibus, 0.034 long. et 0.030 lat., testa 0.0019 mill. crassa, cavitate interna 0.021 lat. et 0.030 long. Habitat. In Canis domesticus, imprimis in Canis lani, fortasse etiam in Canis lupi, tubo intestinali.

Scolex quiescens.—Echinococcus scolicipariens. Vesica minus pellucida, membranacea, in pariete ad 1—2 mill. crassa, ex pluribus 0.005—0.01 mill. crassis lamellis concentricis composita, parvulas gemmas (brood-capsules) stylosas gignens, in quibus scolices singuli proliferantur, magnitudinem 30 mill. et ultra exhibens. Scolices sociales gemmis disruptis libere in vesicam emissi, parvuli, capite Tentac modo dictæ. Metamorphosis in Taniam post 7—8 hebdomades peracta.

Habitat. Interdum in homine, plerumque in aliis animalibus plerumque domesticis ex ordine ruminantium et herbivorarum.—KÜCHENMEISTER in Op. cit., p. 192, 3.

ers, who say that its parietes consist of two similar membranes, loosely connected, the outer being firm and cartilaginous, and the inner thin and smooth, resembling a mucous surface, which is beset with small elevations of a size up to  $\frac{1}{4}$ ", which are partly very young scolices in the act of development, partly farther developed scolices of 1-10", and partly the points on which such scolices formerly sat. In the fluid contained in these vesicles there are also free scolices, part of which are still furnished with the remains of the stalk. For other minutæ of structure I must refer the reader to Dr. LANKESTER's translation of KÜCHENMEISTER's work.

83. This cestode worm is found chiefly in the liver of man and ruminating animals. It has been detected also between the choroid coat and the retina of the human subject. When present in the liver, this organ is generally swollen, especially posteriorly, pale, or of a uniform greyish-brown colour. Its surface presents larger or smaller spots of a whitish-yellow colour, of a regular form, and very slightly raised. The species is generally seated so deeply as hardly to project above the level of the surface of the organ, unless it is very largely developed.

84. d. The symptoms caused by this *Echinococcus* are usually slight, limited, and equivocal. The vesicles seldom exceed the size of a walnut or hen's egg. Even when they are present in numbers, their diagnosis is most difficult. When they are small or few, the disturbance of the functions of the liver may be slight. When more numerous or more fully developed, there are generally pain and uneasiness in the hepatic regions, with increased pain on pressure and percussion; the dull sound on percussion being more extensively heard, and the liver being often felt from one to two inches below the false ribs. There is also irregularity of the bowels, the evacuations being unhealthy, and often deficient in bile. Jaundice is sometimes observed. But of these symptoms may be caused by other lesions of the liver.

85. B. ECHINOCOCCUS ALTRICIPARIENS. *Echin. hominis*, Auctorum.

86. KÜCHENMEISTER\* believes that this species has been confounded with the preceding.—a. Its mature *Tania* is unknown. Nevertheless, he thinks that it probably occurs in the human intestines, and indeed in the intestines of those individuals who suffer, or have suffered, from the species of *Echinococcus* belonging to it in some part of their bodies, and in whom such a colony of *Echinococci* has opened towards the intestine. This *Tania* may also develop itself in the intestines of domestic carnivorous animals. That the eggs and embryos must occur at some time

\* He gives the following definition of its *Scolex*: "*Vesica animata Echinococco scoliciparienti similis sed cm. uno eo multo major (ad  $\frac{1}{2}$  ped. in diamet.)*. Scolices singuli quiescentes majore hamulorum minorum numero (46, 52, et ultra) armati parantur, aut ex modo Echin. scoliciparientis, aut in gemmis aut capsulis a vesicæ matris superficie interna solutis in quibus iterum scolices et vesicæ secundariæ scolices gignendi si præditæ giuntur (mother, daughter, and grand-daughter-vesicles); aut fortasse in vesicis, quæ divisione quadam aut sectione ex vesica matre in vasibus animalis hospitis repente et serpente formantur. Vesica mater nihil aliud est nisi vesicula embryonalis 6 hamulis armata, et valde amplificata; vesicula filia et neptis hamulis 6 destituta, quia ex vesicula embryonalis restituta videtur non exorte sunt.

Habitat. Non solum in homine, sed etiam, auctoribus Haubner et Creplin, in mammalibus majoribus domesticis, et quidem in diversissimis et hominis et illorum animalium corporis regionibus. Ovula, lucusque ignota."

or other in the human body must be admitted, although they escape observation from their small size.

87. *b. The Scolcx*—the *Echinococcus altricipariens*—occurs not only in man, but also in the larger domestic animals, especially herbivora. It is very prevalent in Iceland. Dr. SCHLEISSNER states that he saw fifty-seven human patients suffering from *Echinococcus* in that island; that it occurred more frequently inland than on the coast; and that it constituted one eighth of the diseases of the place. Dr. THORSTENSON, of that island, says that every seventh living human being in it suffers from *Echinococci*; that females are more liable to them than males, and that their abundance increases with age, men being most frequently attacked by them between their thirtieth and fortieth, and women between their fortieth and fiftieth years.

88. *c. The characteristics* of this species of *Echinococcus*, as distinguished from the preceding, appear to be as follows: (*a*) The enveloping cyst, and the mode of annexation of the inner wall of this cyst to the primary vesicle of the *Echinococcus*, derived from the six-hooked embryo, are similar in this and the foregoing species; but the cyst formed by *Echin. altricipariens* is much larger than that of *Echin. scolicipariens*, and hence projects far above the level of the organ in which the colony exists.—(*b*) Owing to its much greater bulk a proportionately increased interference with the functions of the organ results, and eventually with the whole organism.—(*c*) As regards the animal itself, we find not only single scolices or a single vesicle in such a colony, but the constant production of fresh vesicles with young (daughter and grand-daughter vesicles), sometimes with, and sometimes without, the production of separate scolices adhering directly to the walls of the vesicle. According to THORSTENSON and SCHLEISSNER, the hydatids occurring in Iceland exhibit this structure. "The hydatid sacks," they state, "are formed not only in the human liver, but also in many parts of the abdomen, and are often of enormous size. Hundreds of hydatids are frequently evacuated through the external opening of the sac, or with the stools, and in vomiting. They do not, however, occur only in the interior of the body, but also very frequently in the skin, where they appear like large saccular swellings. The course of the disorder is very chronic." KÜCHENMEISTER states that the vesicles produced do not, like the original mother-vesicle, bear six embryonal hooklets, as they never have occasion for them. The six hooklets may be sought for in vain, even in the mother-vesicle, as, although certainly present, they must, from their extreme minuteness, escape detection on such a large vesicle. The smallest of the grand-daughter vesicles are but just visible, and enclose four, five, or more scolices, which adhere peripherally, by a small stalk, to the inner wall of the common cyst, but converge with thin free ends towards the centre of the cavity of the small vesicle. In very large daughter-vesicles scolices also swim about freely.—(*d*) The scolices produced or *nursed* by the mother-, daughter-, or grand-daughter vesicles are in general more slender than those of the preceding species: they have the head with the double circlet of hooks, more frequently protruded during life, at least within the larger daughter-vesicles, exhibit distinctly

marked sucking-disks, and bear a greater number (46 to 54) of hooks, which appear more slender than in the preceding species.—(*e*) The dwelling-places of this species are not limited. They may occur in the liver, the lungs, the kidneys, the sheaths of the testicles, the spleen, the ovaries, the breasts, the throat, in the sub-cutaneous tissues, in the bones, &c.—(*f*) With the increase of the secondary and tertiary cysts in the mother-cyst the swelling advances; and the more rapidly this takes place, the recognition of the malady and its natural cure are facilitated; inasmuch as the mother-cyst is often burst by the distention, and probably in many cases becomes destroyed. Sometimes, however, the burst colony appears to heal and to recommence the production of fresh daughter-vesicles.

89. *d. The prognosis* of this species is more unfavourable than that of the preceding, "although the *diagnosis* is easier, on account of the more rapid growth and greater bulk of the swelling, the occurrence of the hydatid-buzzing, and the more distinct sensation of fluctuation. The structure of the walls of the mother-vesicle is the same in both species, and is characterized by the numerous parallel concentric layers in the substance of the walls, which appear more distinctly marked in the daughter-vesicles, and make their appearance with remarkable clearness after treatment with caustic potash, with the addition of a drop of red ink." (LANKESTER's *Transl. of KÜCHENMEISTER*, &c.)

90. *e. The Diagnosis of Echin. altricipariens*.—The symptoms produced by a colony of these parasites vary with the organ in which it is located, and with the size and pressure of the tumour it develops. At an early stage of their growth these animals generally occasion little inconvenience, and when largely increased in bulk they produce phenomena which vary little from those occasioned by tumours of the same size in similar situations. Their superficial or deep-seated positions, and their vicinity to, and pressure upon, nerves and blood-vessels, will also modify effects, or even indicate their existence. But it is comparatively rare to obtain certain evidence of the presence of a colony of *Echinococcus* in the body, unless the passage of the gelatinous vesicles already described from the cavities after the bursting of such a colony, or from the punctures or incisions made into tumours. At the same time, the little scolices of the *Echinococcus* must be found in the vesicles, part of these retaining, others wanting their hooks, their sucking-disks being often indistinct. When the vesicles passed have an opening, the little scolices slip out very easily, and if the structures just mentioned be not found, it is doubtful whether or no a steril colony or an acephalocyst be present.

91. Before perforation or bursting of the cyst has occurred, the tumour produced by it being very considerable, an examination of it should be made by palpation and percussion, and if there be an obscure or sensible fluctuation, and when aneurismal symptoms are wanting, and when the general health is either good, or not injured to the extent that might be expected from the size of the tumour, if it were of a malignant nature, then an explorative puncture should be made to complete the diagnosis, and the evacuated fluid examined by the microscope in order to ascertain the presence of *Echinococcus scoliceis*, or of albuminous gelatinous shreds of *Echinococci*. By

these means only can the nature of a cystic or saeculated, fluctuating or elastic tumour be determined, and the existence of these parasites ascertained.\*

92. Without these proofs the diagnosis can never be brought beyond one of probability. A saeculated or cystic swelling filled with fluid can alone be inferred. The most useful objective symptoms are the existence of such a tumour, which is elastic to the touch, and of a peculiar consistency and form, in places where swellings do not usually occur; but when these do make their appearance, they are generally *Echinococci*. The highest degree of probability that an unopened tumour belongs to a colony of *Echinococci* is attained when the swelling occurs in places such as the liver, spleen, kidneys, lungs, breast, testicles, throat, &c., where *Echinococci* are otherwise brought to light, either artificially or naturally. On percussion, the finger, placed over the swelling, often feels a trembling or oscillation of the mass underneath it, especially when several gelatinous tremulous cysts are enclosed within a larger vesicle; these being set in

\* ACEPHALOCYSTS.—LAENNEC, in 1804, viewed these structures as independent animal organisms. VON SIEBOLD and KÜCHENMEISTER more recently opposed this view; and very lately the last of these writers, in consequence of his experiments with the eggs of *Tænia*, considered that *Acephalocysts* are six-hooked cestode embryos, the growth of which has proceeded without hinderance, but which, nevertheless, have remained barren; or, more correctly, which have never attained to proliferation and the production of scolices.† If *Acephalocysts* occur where normally-developed *Echinococci* usually have their abode, they cannot be called stray cestode embryos, but only cestode embryos which have been disturbed in their normal development and remained barren. KÜCHENMEISTER considers the following to be the characteristic marks of *Acephalocysts*: 1st. A vesicle adhering to the inner walls of a larger cyst from which it is capable of being detached, or is already detached, in particular spots, but never all over, and collapsed in wrinkles, and which presents very sparing calcification in its white and scarcely discoloured walls. 2d. The transverse section exhibits walls consisting of distinctly developed, parallel, concentric layers. 3d. The walls have a peculiar elastic gelatinous trembling. 4th. The contents consist of a watery fluid, or of a substance of a purulent consistence, and contain the microscopic elements of calcifying encysted protein masses in the act of resorption. 5th. The vesicle sometimes conceals, in its interior, secondary cysts, with gelatinous walls, in which, however, we seek in vain for scolices of cestodes or their remains, especially their hooks. "The *Acephalocysts* which are referred to here belong to the following three species of *Tænia*: 1. *Acephalocysts* derived from *Tænia Echinococcus scoliciparus*. Many of those *acephalocysts* which bear no daughter-vesicles in their interior must be referred to this species. 2. *Acephalocysts* derived from *Tænia Echinococcus altriciparus*. These are *acephalocysts* with a formation of daughter-vesicles. 3. *Acephalocysts* derived from *Tænia ex Cysticercus tenuicollis*." KÜCHENMEISTER remarks respecting these last that what ESCHRIEUT regarded as possible has since proved to be the case; for that in one administration of eggs of *T. ex Cyst. tenuicollis* to a lamb, he found a sterile *Cysticercus tenuicollis* in the midst of other equal-sized and fully-developed *Cysticerci* of this species. This sterile individual bore perfectly distinct indications of life. All structures, he adds, which are really *acephalocysts*, and which are living sterile specimens of *Cysticerci* and *Cœnuri*, are distinguished from those derived from *Echinococci* in that the walls of the latter consist of very distinct concentric layers, tremble like jelly, and are extraordinarily elastic; while the walls of the analogous structures derived from *Cysticerci* are considerably thinner, have not the elastic consistence of jelly, and consist of such fine and delicate concentric layers as hardly admit of detection. Such being the origin and nature of *Acephalocysts*, it is obvious that the phenomena produced by them cannot be materially different from those caused by the two species of *Echinococcus*.

The subject of *Acephalocysts* has been already treated of under the article LYDIDIDS; but instead of viewing them as in that article, as independent organisms, the more recent Continental microscopists and experimenters have shown them to originate as now stated.

motion by the percussion, appear to produce this trembling or oscillation, which, however, frequently is not felt.

93. *f. The etiology of the Echinococci* is manifestly the ingestion of one or more of the eggs or six-hooked embryos of the *Tænia Echinococcus altriciparus* at some time of the life of the patient. The mode of life of persons in some localities and in some circumstances may be favourable to the passage of the eggs of this *Tænia* into the stomach; and it is now well understood that certain *Cestodea* often have a very limited habitat. "The duration of the life of the *Echinococcus* does not appear to be very short. According to ESCHRIEUT, one patient must have borne his colony eighteen years."

94. *g. The prognosis of the Echinococci* varies according to the organ in which they are seated, to their situation in that organ, and to the primary and consecutive injuries caused by them to the organ and to the whole system. But the prognosis is upon the whole more favourable than is generally supposed, especially when the general health and the powers of vital existence are duly promoted. "The tumours, when they are accessible, are among the number of curable tumours; they may cure themselves by bursting, and when they are once got rid of relapses in the same colony are rare and exceptional cases, and every *Echinococcus* produced usually owes its existence to a new immigration of embryos. But for this very reason the continuance of the mode of life in endemically affected places furnishes a more unfavourable prognosis. The natural cure by the bursting of the colony, and the passage of daughter-vesicles, may be accompanied by symptoms dangerous to life, or, if it take place in the direction of the larger bronchi, by difficulty of breathing, or may even lead to actual suffocation." (*Op. cit.*, p. 227, 228.)

95. *B. Sub-order, TREMATOIDEA.—SYNON.—Myximitha, DIESING; Egghwürmer; Platyhelmintha isolata, Isolated flat-worms, KÜCHENMEISTER.*

DEFINIT.—"*Animalia solitaria, plerumque hermaphrodita, rarissime sexu distincto. et poris plerumque suctorius, medianis aut laterahbus instructa. Canalis cibarius furcatim divisus aut ramosus, rarissime simplex. Evolutio fit plerumque metamorphosi et sapissime generatione alternante, rarissime sine illis.*"—LEUCKART.

96. This sub-order is divided by KÜCHENMEISTER into two Families, the *Monostoma* and the *Distoma*.

97. (a) *MONOSTOMA.\*—SYNON.—Cucullanus; Festuaria; Fasciola; Amphistoma; Distoma; Monostoma; Monostomum.*—It is very doubtful whether or no any species of *Monostomum* has been found in the human body. Professor JÜNGKEN was said to have found eight *Monostoma* in

\* "*Corpus depressum vel tereusculum. Caput continuum, vel collo discretum. Os terminale vel anticum, ut plurimum acetabuliforme, integrum, crenulatum, interne vel armatum. Apertura genitalium perclara, duplex; mascula infra os, interdum acetabuliformis, pene protractilis; feminea pone masculum, minima, ut plurimum inconspicua. Porus excretorius supra caudæ apicem antice margine caudali. Animalia manna nalia, avium, amphibiorum et piscium corpora, i. e., præter tractum intestinale organa varia inhabitantia, libere aut folliculis inclusa.*" (DIESING.) *Metamorphosis et generatio alternans inter evolutionem, uti in Distoma.* The ventral sucker is therefore deficient, and DIESING gives a warning, "*Cave, ne Bothriocephalidearum articulum solitarium pro 'Monostomum' habeas, aut porum genitalen, interdum callosum, cum acetabulo confundas.*"

an incipient cataract; and hence VON NORDMANN named the species *Monostomum lentis*.

93. (b) *DISTOMA*\* (KÜCHENMEISTER); *Distomum* (DIESING).—*a. Distoma hepaticum*†—*Distomum hepaticum*—The fully-developed *Distomum hepaticum* has been minutely described by KÜCHENMEISTER, but I must refer the reader for his description to his work, or to its excellent translation by Dr. LANKESTER.—*a.* I may, however, briefly state that its *skin* and *parenchyma* consist of muscular layers—of longitudinal, transverse, fusiform, and short fibres; that its organs of sense are wanting, and its nervous system has not been described; that its alimentary apparatus presents a mouth, pharynx, and excretory organ; that its *female* sexual organs lie towards the ventral surface of the animal, and consist of a germ-stock, with its efferent duct, two vitellines, a short oviduct, a sac-like uterus, and a vagina; that its *male* sexual organs consist of testicles, a ductus spermaticus, a vesica seminalis, and a penis; and that “the *Distoma* are hermaphrodites, with the following sexual actions: self-impregnation with and without copulation, and impregnation and copulation with a second individual.” This *distoma* occasions great devastation in the livers of herbivorous and domestic animals, especially in wet seasons; but it very rarely occurs in man.

99. *b. Diagnosis*.—*Distoma* in the liver causes dilatation and inflammation of the gall-ducts, and destruction by pressure and disappearance of large portions of the parenchyma of the liver in the vicinity of the enlarged ducts. These changes, however, cannot always be recognised, or referred to their true source in the human subject, as several lesions of the biliary organs and apparatus occasion the same symptoms as they produce. The *distoma* may even cause many

of the phenomena of gall-stones passing along the ducts, with or without more or less of jaundice; but these cannot assist in establishing a diagnosis, the passage only of the animals with the fæces or with the matters vomited being the only proof of their presence in the human subject.

100. *c.* It is obvious that no *prognosis* of the *Distoma* *malady* can be formed unless the animal be discharged and recognised. When this takes place, although the prognosis is upon the whole unfavourable, yet there may not be any immediate danger. The life of the patient may be prolonged, or even a recovery ultimately obtained, by promoting the secretions and excretions by suitable means, and by supporting vital force and resistance.

[Several years since we prescribed for a railroad engineer in the State of Ohio, who complained of a sensible movement in the epigastrie region, with considerable derangement of the digestion, loss of appetite, pain, anorexia, bilious symptoms, &c. He said he was positive there was a living animal in his stomach, which he had probably swallowed while drinking at some of the stagnant pools while pursuing his vocation as surveyor and engineer. Meeting him some months after, he stated that he had passed the animal after taking a powerful purgative; that it was from three to four inches in length, flat, alive, and of a dark colour, &c. It was evidently an enormous *Distoma*. In the same region of country, the livers of animals, especially the ox and sheep, and frequently the hog, are infested with the same parasites under the name of *fluke-worms*, which frequently prove destructive to life. We have often seen the ox liver perforated by these animals like a honey-comb.]

101. *β. Distoma lanceolatum*\* (MEHLIS). This species was seen in the human subject by BUCHOLZ, CHABERT, and MEHLIS. It is narrow and elongated, and distinguished by its long neck, by the want of any spinous coat, and by the female organs especially occupying the abdomen, and the testicles the anterior part of the body. SCHAEFFER, RUDOLPH, and MEHLIS established this as a distinct species of *Distoma*, and showed that GÖRZE, ZEDER, and BREMSER were wrong in re-

\* “Corpus depressum vel teretiusculum, armatum vel inerme. Caput continuum, vel collo discretum. Os terminale, vel anticum, ut plurimum aet. bulbiforme. Acetabulum unum ventrale sessile, vel pedicellatum, medianum, ab extremitate postica plus minusve remotum. Aperturæ gentilis approximatae, scississimæ ad exitum conjunctæ (clonæ instructæ), supra vel infra acetabulum sitæ. Antennæ plerumque hermaphroditicæ, rarissime siccæ distinctæ. Ovid. embryones pœntibus rarissime similes, plerumque dissimiles aut fimbriatos, aut fimbriis destitutos continentes, quare evolutio sit metamorphosi et generatione alternante.

“Statu immaturo aut libere in natura vagantia, aut in organorum p. enchymate, imprimis in animalibus inferioribus inclusa. Statu maturo endoparasita animalium propriis vertebratorum, aut libere in variis organis et cavitatibus apertis et clausis viventia, aut in folliculis inclusa.”—DEJARDIN et DIESING.

\* “Corpus plenum, armatum, saltem in juvenilibus, et majus profectū adhuc in collo. Individua juvenia 4”–9 mill. longa, 1”–3.3 mill. lata; adulta 8–14”–18–31 mill. longa, 3½–6”–8–13½ mill. lata.

“Collum subconicum, breve. Os hanc rotulosum, terminale, triangulare, 1.4 mill. latum. Acetabulum 1.5 mill. latum, os majus superum ad colli basin, aperturæ triangulæ, 3–4 mill. pone os situm.

“Organis genitalia fere contigua, mediū in parte inter os et acetabulum sita. Penis cylindricus, 3 mill. longus, 0.5 mill. latus, fulciformis, prominens, uncinulis parvis armatus. Testiculi macinā ex parte mediū in corporis posteriori parte siti, ex trunco medio et ramificationibus, ad finem cæcis, compositi. Organa vitellina ad latera animalis sita, inter se horizontali quodam et transverso ramo conjuncta et statim in utrum simplicem magnitudine crescentem, multifarie volutum transcurrentia. Ovid. flavū, infra quendam porculam ad obsequio, delatens, 0.055–0.063” (V. et Par.) = 0.126–0.144 mill. longa, et 0.035–0.038” = 0.079–0.086 mill. lata.

“Embryones Cercarum atriculi aut Iridie, nec minus Cercarie libere, si omnino hæc forma præbeatur, ignote. Migratio nūn modum nonnullis committitur. Distomum juvenile immaturo semel sub cute humanā inventum.”—KÜCHENMEISTER.

\* “Corpus leve, lanceolatum, planum, aliquid p. hercidum, ad oris flavofuscum, 4.5–12 millim. seu 2–6” longum, 2 ad 2.3 millim. aut 1–2” latum in anteriore parte tenuius, acetabulo fixatum, in posteriore aliquid obtusum. Collum continuum, conicum, planum, longius quam in D. hepatico. Os fere terminale, globosum, 0.45 mill. latum, acetabulum orbiculare, 0.43 mill. latum, 1.1 mill. pone os situm, os majus. Oesophagus 0.45 mill. longus, bulbos oesophagi 0.10 mill. latus; intestinum bifurcatum, rectum, simplex, non amplius ramificatum, 0.04 mill. latum.

“Genitalia intra os et acetabulum ventrale sese aperientia, inter intestini bifurcationem sita. Vesica seminalis exterior=cirrus claviformis; funiculus spermaticus flexuosus; penis longus, cylindricus, plerumque rectus; testiculi 2 majores et tertius minor vesicam seminales internam exhibens; unus pone alterum et pone acetabulum ventrale siti, vix lobati. Organa vitellina multo minora, quam in D. hepatico, albida, lateralia, ramificata, 1–1½ mill. longa, in ovarium et uterum intrantia, longiora quam in Dist. hepatico et tenuiora, ad colore obscuriore prædita, multifarie voluta. Ovid. multo minora, quam in Dist. hepatico, 0.041 mill. = 0.018” Par. 0.0185” Vienna longa, et 0.0246 mill. = 0.0108” Par. 0.011” Vienna lata, sed in statu maturo multo obscuriora quam in D. hepatico, et nigro-rubra.

“Systema excretorium: Vasa lateralia, ad collum usque prominentia, ibique recurrentia et intumescunt in minora, ad animalis apicem sita, finita.”—KÜCHENMEISTER.

garding it as a young *Distoma hepaticum*. It is stated by KÜCHENMEISTER to be less injurious to the structure of the biliary apparatus than the *D. hepaticum*. The diagnosis is possible only when it passes off. The prognosis is probably more favourable than in the case of the other parasite.

102. *γ. Distomum heterophysis*\* (VON SIEM-BOLD).—This parasite has hitherto been found only in two instances, but in very great numbers, in the small intestines, by BILHARZ. Its influence on the animal economy is unknown. It is unnecessary to give a farther description of it than that contained in the subjoined definition.

103. *δ. Distomum hamatobium*† (BILHARZ).—*a.* This parasite was first found in 1851, in the blood of the portal vein. It appeared as a white elongated entozoon, resembling a nematoid worm when examined with the naked eye; but was found to be *Distomum*, with a flat body and a cylindrical tail ten times as long as the body. This tail was no loosely attached, deciduous portion of the body, as in the *Cercaria*, but a continuation of the body of the worm itself, which was flat and rolled towards the ventral surface. This first animal found was clearly recognised as the male; another subsequently found in one of the mesenteric veins of the same subject was ascertained to be the female. For a minute description of the sexual organs, eggs, and development of this animal, I must refer the reader to KÜCHENMEISTER'S work. It may, however, be stated that, according to Professor GRIESINGER, this parasite is so extraordinarily abundant in Egypt as to have been found 117 times in 363 dissections. It would appear that the *Distoma*

get into the blood-vessels and lay their eggs, which at last escape from the ruptured vessels in the intestinal and urinary mucous surfaces. Dr. REINHARD saw, hanging out of a vessel accidentally opened by KÜCHENMEISTER, one of these *Distoma*, which bore his female with him. The action of their eggs and embryos on the mucous coat of the intestines and urinary organs, and on the biliary apparatus, is of a very dangerous nature.

104. *b. In the intestines* are found deposits upon and beneath the mucous membrane, verrucose and lobate fungous excrescences, and also the aggregations of the eggs in the vessels of this membrane, "where the eggs are often fixed in rows in the mucous and sub-mucous tissues, in and beneath the croupous exudations upon the intestinal ulcers; and, lastly, after the rupture of the vessels upon the free surface of the mucous membrane."

105. *c. Action on the Liver*.—"The entire trunk of the portal vein is sometimes filled with mature animals, with eggs in the substance of the liver; and it is not impossible that the *Distoma* situated in these places may give rise to a tough, dry, anæmatus consistence of the liver, or perhaps even to abscesses."

106. *d. The alterations in the urinary bladder* produced by *Distoma hamatobium* are at first circumscribed spots of hyperæmia, with bloody extravasation and swelling of the mucous membrane, or tenacious mucus, with grayish-yellow masses of exudation, in which the eggs are imbedded. "It is rare that the whole inner wall of the bladder is injected and ecchymosed. The urine is mucous, but pale and clear; and BILHARZ found eggs in the urine passed." In later stages, yellowish discoloured elevations, mixed with many pigment spots. These elevations often form a soft coat, sometimes a line in thickness, mixed with bloody extravasations, firmly attached to the mucous membrane. Sometimes calcareous incrustations of the egg-shells, the deposition of the salts of the urine, and the aggregation of eggs, give the whole a sandy texture. Very rarely this coating covers true ulcers with loss of substance. At other times, single or aggregated vegetations, varying from the size of a pea to that of a bean, of a yellowish colour or ecchymosed with blood, are found on the vesical mucous surface. In the smooth-edged spaces of these vegetations, sitting in the sub-mucous tissue, formed by the diverticula of its vessels, and only constituting productions of the vessels, BILHARZ first found the *Distoma*, and in the mucus and exudation over these spots their eggs. We may conclude from this that the *Distoma* collect there, and in similar situations, to lay the eggs which are to be passed off.

107. *e. The mucous membrane of the ureters*, either alone or with that of the bladder, or even with that of the pelvis of the kidney, in rare cases, is attacked in a similar manner. A gravelly matter, in molecular masses of imbedded eggs of *Distoma*, either empty or containing embryos, with blood, exudation corpuscles, and crystals of uric acid, is sometimes passed in the urine. Individual embryos also occur free, but GRIESINGER found these in a dead state only. In consequence of the thickening of the inner coats of the ureters, complete or partial occlusion of these ducts with dilatations above it, with retention of urine and its consequences, sometimes supervene.

\* Descriptio.—"Dist. heter., hermaphroditum. Corpus orato-oblongum, depressum, subtus planum, supra leviter convexum. Aetabulum oris subapicale, infundibuliforme, parvum. Aetabulum ventrale paululum ante medium situm, magnum (aetabulum oris decies et ultra superans), globosum. Pharynx muscularis, globosa; canalis cibarius ante aetabulum ventrale in 2 partes cæcæ divisis. Cirrus post aetabulum ventrale situs, et oblique eum sinistrâ ejus parte cohitus, globosus, aetabuliformis, circulo incompleto setarum 72 minutissimarum, ramulis 5 secundis instructum coronatus, testiculis organoque germinifero globosis. Longitudine 4—4½; latit. ½."

† Patria.—Egyptus; in hominis intestino tenui bis reperiuntur, numero permagno."—KÜCHENMEISTER.

‡ Descriptio vermis secundum BILHARZ.—"Distomum hamatobium, sexu distincto. Moris corpus molle, albidum, filiforme, parte anteriore totius longitudinis octava vel nona ('truncus') depressa, lanceolata, subtus plana vel concava, supra leviter convexa, superficie levî, reliquis corporis parte ('cauda') terete, margine corporis ad aetabulum ventrale retro utrinque versus faciem ventralem conflexo, eoque modo canalem gynæceophorum, efficiente, apicè postico, attenuato, superficie externa tuberculis piligeris conferta, superficie candida interiore linea mediana levî et partibus lateralibus aculeis minutissimis scabra. Aetabulum oris apicale subinflexum, triangulare. Aetabulum ventrale sub finem 'trunci' inserum, orbiculare eadem magnitudine cum aetabulo oris. Superficies utrinque aetabuli granulis crebris minutissimis scabra. Canalis cibarius sine pharynge musculari ante aetabulum ventrale in 2 partes divisis, in posteriore ('caudâ') parte demum unitus, cæcus. Porus genitalis inter aetabulum ventrale et canalis gynæceophori originem situs."

"Femine forma dissimilis, teneriora, gracillima; corpus teretiforme, larve, hyalinum, antice sensim valde attenuatum, cauda canali mullo apicè angustata. Aetabulum oris apicale cibarius, ut in mare. Porus genitalis cum margine posteriore aetabuli ventralis cohitus."

"Longit. 3—4 lin.; mas feminam latitudine multo superans."

"Patria.—Egyptus; in hominis vena portuum ejusque ramificationibus et in vesicæ urinariæ parietibus. In renis mesenterico reperiuntur mares feminam in canali gynæceophoro gerentes, in renis intestinalibus et hepaticis, in vena lienali semper reperiuntur."

The kidneys are somewhat swollen and congested with blood, and the mucous membrane of the pelvis is much injected. The kidneys, in rare instances, ultimately degenerate in a fatty or suetty state. "The aggregation of eggs of the *Distoma* are not unfrequently the nuclei of deposits of gravel and stones, consisting chiefly of crystals of uric acid in the kidneys, ureters, and bladder, and thus give rise to the well-known consequences of stone and gravel. This is the *Lithiasis* of the Egyptians, described by PROSPER ALPINUS in "*Medicina Egyptiorum*."

103. The seasons appear to have some influence upon the frequent occurrence of this worm, as it has been observed to be more abundant from June to August, and more rare in September, October, and January. This difference is probably owing more to the kind and quality of the food in these months, than to temperature or season.

109. *f.* The symptoms of this parasite are manifested chiefly in the urinary apparatus, and in the urine itself, at an early period of the lesions produced by it. Causeless hæmaturia, especially if frequent, and attended by æmia, emaciation, and disordered bowels, should be a cause of suspicion, especially in tropical countries. The diagnosis, however, during life, can be certain only when the eggs are found in the bloody urine and in other evacuations, as they were by BILHARZ.

110. *ε.* *Distomum ophthalmobium*\* (DIESING).—This parasite was found in the eye of an infant, between the lens and the capsule, by GESCHIEDT. The infant was five months old, and was born with *cataracta lenticularis*, with partial suffusion of the capsule. Four specimens of this *Distoma* were found, and were recognisable by the naked eye.

ii. Order, NEMATELMIA—NEMATODEA.—Thread worms, Round worms.

111. The worms now to be treated of are the *First Order* of RUDOLPH.—"Nematodea: *Corporis elongato, tereti, elastico*." DIESING, in his "*Systema*," arranges them as the *Sixth Order* of his *first sub-class*, and defines them—"Nematodea: *Corpus clasticum, cavum, subcylindricum; tractus cibarius simplex, caput in proboscidem haud protractile. Endoparasitica, tandem rarius exus libere vagantia*." They form the *second order* of KÜCHENMEISTER's *second sub-class*, and he defines them as follows: "NEMATELMIA: *Corpus teres, clasticum, sæpe attenuatum, filiforme; ore centrali, vel sub-centrali; canalis cibarius aut distinctus aut obsoletus, anoque destitutus. Metamorphosis in paucissimis. Migrationes activæ aut passivæ in permultis*."

112. *Mature Nematode worms* are met with in the human subject in the cavities of the body, having mucous surfaces, in the sub-cutaneous cellular tissue, with an artificial external communication, and during their youth, and in an immature state, in various muscles, especially primitive muscular fasciuli. The division of this order of worms into numerous genera and species has been attempted by DUJARDIN, VON SIEBOLD, DIESING, and others, but without sufficient agreement to admit of further reference to it than is made by KÜCHENMEISTER, who does not adhere to a strict classification, but rather re-

views them in accordance with their dwelling-place in the human body, and selects for them the name most generally employed. It was formerly thought that the *Nematodea* were the most accurately known of *Entozoa*, but at the present day we have more positive knowledge of the history and development of the cestode worms, and even of the *Trematoda*, than of this, the order of round worms.

113. "The distinct presence of a digestive apparatus, divisible into mouth, œsophagus, stomach, intestine, and anus, the separation of the sexes into two individuals, the certain detection of a nervous system in some of them, and the apparently jointed structure of the round worms, bring them near to the articulata. In the human subject we must take into consideration: 1, the *Trichocephali* and *Trichina*; 2, the *Oxyuri*; 3, the *Strongyli* and *Ancylostoma*; 4, the *Filaria*; and, 5, the *Ascarides*." (Op. cit., p. 289.)

114. A great part of the nematode worms appear to reach maturity only after they have undertaken various immigrations and emigrations during their youth. One species of round worm common to man is to some extent capable of migration also in the mature state. The migration in the early stage of development consists of the escape outward of the eggs of these worms with the human fæces, with which they get into dung-hills, sewers, &c., and experience the transitions described above (§ 7, et seq.). My limits admit not of an account of the sexual and other organs of this order of worms, and of the various stages of their development; sufficient reference to these topics for practical purposes has already been made, and the reader may farther peruse the minute descriptions of KÜCHENMEISTER and VON SIEBOLD, and of other recent observers, to whom I have referred.

i. TRICHOCEPHALUS.\*—SYNON. *Trichuris*, RÖDERER; *Ascaris*, LINNÆUS; *Mastigodes*, ZEDER; *Trichocephalus*, GÖTZE, DIESING, DUJARDIN, &c.

SYNON.—*Trichocephalus dispar*, GOEZE; *Trichuris*, ROEDERER and WAGLER; *Ascaris*, LINNÆUS; *Mastigodes*, ZEDER; *Trichina*, FILARIA, Auct.; *Trichurc*, Fr.

116. A. This worm was first discovered by MORGAGNI in the cæcum and vermiform appendage of typhous patients; and ROEDERER and WAGLER, in 1761, recognised it as a distinct worm, in the “*morbus mucosus*,” or mucous fever, so prevalent in Germany in the middle of the 18th century. It was long supposed to exist only in the intestines of typhous patients, but it is now fully ascertained to have no particular relation to any disorder of the human bowels. It is found chiefly or only in the lowest region of the small intestine, near the ileocæcal valve, in the cæcum, and colon. From the dingy colour of the worm, it is liable to escape detection, and only is detected with ease when the lower intestines are free from their thick and coloured contents, as in disorders attended by diarrhœa. If carefully sought after, these worms will be found more frequently and in greater numbers than is commonly believed. RUDOLPH found many hundreds in the situations just named. BELLINGHAM saw upward of 100 in the cæcum only of one patient in Dublin. They occur in both children and adults, and in Europe and Africa. KÜCHENMEISTER’s work and its translation by Dr. LANKESTER, contain very minute descriptions of the organization of this parasite. The subjoined systematic description is sufficient for all practical purposes.

117. *B. Trichina spiralis* (OWEN and LUSCHKA), as the brood of *Trichocephalus dispar*, engaged in migration.—This asexual worm was first described by OWEN in 1835, although previously seen by TIEDEMANN in 1822, and by HILTON and WORMALD in 1833. It was afterward seen and described by PAGET, KNOX, and others. The seat of this worm is, as is well known, the muscles of voluntary motion, and indeed all the muscles excepting the heart and the sphincter ani, where it has not yet been found. In the places where capsules of *Trichina* are seated, fatty tissue is constantly inserted, chiefly at their

anterior and posterior extremities; the fat being apparently deposited to fill up the space produced by the *Trichina* having penetrated between the muscular fibres.

118. a. The development of *Trichina spiralis* seems to be as follows: “When a human being has swallowed the eggs, or the youngest brood developed into ready-formed embryos which occur in the eggs, or perhaps also when any female *Trichocephali* residing in the small intestine scatter their eggs with the ready-formed embryos in them, and when in either case the egg-shells are burst, and the embryos set free in the intestinal canal, the desire of migration awakens in them, and they set out, like the embryos of many other *Nematoda*, in the shortest and easiest way towards the tissues which they prefer as their resting-place.” That in this case, as in that of the *Cestoda*, the digestive canal may be the place of immigration from the exterior, is shown by the fact that the muscles of the tongue, pharynx, and œsophagus, as well as the sphincter ani internus, are visited by the *Trichina*. In some cases the blood may be the bearer of the migrating brood. MEISSNER found the young attached to the inner walls of blood-vessels of the heart; and both he and LEUCKART think that the circumstance of the brood of cestode worms being found so abundantly in the blood-vessels shows that the blood is their most usual course of migration. KÜCHENMEISTER believes that both courses of migration are followed—penetrating the tissues, and by the blood. The *Trichina* having found a resting-place, a cyst closely adhering to the tissues is formed around it. This cyst consists of concentric layers of a fibrous or lamellar substance, with imbedded nuclei. The brood reposing in this cyst approximates the head and caudal extremities in spirals, without, however, contracting a part of the head, and is then perhaps surrounded, even on the part of the worm, with a peculiar layer, but certainly enveloped on the part of the host with a capsule and cyst, in which the worm increases in size; and, besides the intestinal canal, develops the primitive foundations of an organ which belongs to the generative apparatus. The material for the capsule or cyst enveloping the *Trichina*, according to LUSCHKA, is formed from the inflammatory exudation produced by the passage and site of the worm; and hence the cyst varies in appearance with the time which has elapsed since the immigration, the oldest cysts exhibiting granules of lime-salts combined with an organic substance, this deposition of lime-salts increasing with the age of the cyst. SANDERS and KIRK state that there are around the worm—1, an external fibrous envelope; 2, a tolerably thick layer of a white, transparent, homogeneous substance; and, 3, an internal round capsule.

119. b. The contents of the cyst consist of one or more animals, and a small quantity of fluid, which keeps the inner envelope extended (which envelope KÜCHENMEISTER and LUSCHKA believe to be derived from the animal itself); the fluid is sometimes clear, especially in the comparatively young *Trichina*. In cysts with worms recently dead or destroyed, it showed traces of organic decomposition. In cysts with worms which have been long dead, or in those which contained no worms, which are rare, is found a clear, thickish fluid, with small formative elements, or only a

few elementary granules. These wormless cysts probably had previously enclosed a *Trichina*, which had died, and that a complete solution of the worm had taken place, or which had migrated from the cyst, and wandered to some other situation, where it had again become encysted.

120. As to the destination of the *Trichina*, there is no doubt that a great number, if not all, of those which occur in the muscles of man become abortive and die. The latter then lie in their cysts, in the midst of the cyst-fluid, which is in course of sebification, desiccation, and calcification, rolled in spiral convolutions, in the same way as the *Trichina* seen in a living state. These spiral structures are, however, broken up into fragments, which indicate a ringed appearance, or a segmentation of the bodies of these animals. "But how these encysted nematode worms, with our present state of civilization, can reach, before the period of their death—which, however, only occurs very late, perhaps in 30 to 40 years, or after a still longer period in particular cases—places in which they are in a position to pass through their father and higher development, is beyond my power to divine" (KÜCHENMEISTER). On this subject the experiments of this writer, and of ZENKER and LEUCKART, have thrown no light.

121. *c.* The reasons which have induced KÜCHENMEISTER to regard the *Trichina* of OWEN and LUSCHKA as the young brood of *Trichocephalus dispar*, and to consider both these nematode worms, hitherto placed separately, as belonging to one species, are the following: 1. The skin of both has a peculiar ringed and jointed structure, which presents itself more distinctly than in many other *Nematoda*. 2. In both, a longitudinal stria runs down the sides, indicating the limit to which the contractile parenchyma of the worm, in which its internal organs are imbedded, reaches. These striæ are certainly the points of attachment of the parenchyma to the inner wall of the integument of the *Trichina*. 3. The alimentary canal is organized in exactly the same way in both. The mouth and anus are situated exactly in the centro of the two extremities of these bodies, the anterior and posterior; this circumstance excluding the *Ascarides*, *Oxyurides*, and *Strongyls*, and most of the *Filarie*, from any relationship with *Trichina spiralis*. 4. The second tube which occurs in the abdomen, together with the intestinal canal, favours the identity of the two worms; the course of this tube admitting of being so developed as to produce either female or male *Trichocephali*. For these reasons KÜCHENMEISTER regards the *Trichina* as the brood of *Trichocephali* engaged in migration, by swallowing which we infect ourselves with the *Trichocephalus dispar* of both sexes. The symptoms produced by these worms have not been observed or stated. Even the immigration of the brood of *Trichina* appears to take place without any general reaction, and is also borne without injury for many years.

122. ii. OXYURIS = sharp-tail (from *ὄξύς* and *οὐρά*). This name applies only to the female, but by no means to the male. This worm is differently classed by DUJARDIN and DIESEN, whose classifications are too artificial, and too subdivided to admit of notice at this place. The *Oxyuris*, according to DUJARDIN and most other authors, is a genus of *Nematoda* separated from

*Ascaris*. This writer gives the subjoined systematic description of it.\*

123. *A. Oxyuris vermicularis*, BREMSER, DUJARDIN, VON SIEBOLD, GOEZE, RUDOLPHI, DIESEN, &c.; *Fusaria vermicularis*, ZEDER; *Kinder-, Mastdarin-, Madenwurm*; Thread worm.†—*a.* Three forms as to size, sex, &c., of these worms are met with: 1. The mature females, which are

\* "*Corpus cylindricum aut fere fusiforme, sublongum, in feminis retrorsum subulatum; caput incrne; os rotundum (in statu contractionis) aut triangulare (in statu actionis), trilabiatum; œsophagus musculosus cylindricus aut claviformis et canali triquetro perforatus; ventriculus globosus cavitate triangulari; intestinum in feminis ante apicem caudæ acutæ, in maribus in centro caudæ apertum.*

Embryones viventes in oculis nondum vidi.*"—KÜCHENMEISTER.

remarkable for their size, thickness, and whiteness, for their acute capillary tail, and for an obtuse, broad head. 2. *The young immature females* resemble the pale-gray colour of the males, but they are somewhat larger than they, and are recognised by their acute tails, and by the female sexual organs in grades of development varying with their age. 3. *The mature males* are remarkable by their pale silver-gray colour, and their obtuse anterior and posterior extremities, as also by the penis. All the three forms occur abundantly in one and the same intestine. The skin, head, and œsophagus, and intestine are similar in both sexes. The nervous system of the *Oxyurides* is, according to WALTER, greatly developed, although hitherto overlooked. They have both cephalic and caudal ganglia, with other ganglia, plexuses, and lateral filaments, which are minutely described by WALTER and KÜCHENMEISTER. The primitive nervous filaments are produced from the processes of the ganglionic cells; by the union of several primitive filaments of this kind, narrower or broader branches are produced. The skin of the oxyurides consists of an external *epidermis*, and beneath this a delicate but densely fibrous corium. The *parenchyma* of the body does not extend into the tail. The *muscular system* is highly developed. The *alimentary apparatus* consists of a mouth, œsophagus, stomach, intestine, rectum, and anal cleft. For a minute description of these and of the sexual organization, my limits oblige me to refer the reader to the works of the authors just named, who ascertained that the males of the oxyuris vermicularis are much more numerous than was formerly supposed.

124. *b. The locality* of these worms in the human body is the lower portion of the intestinal canal, especially the rectum. They occasionally stray upward, but rarely higher than the lower part of the small intestine. They wander, however, out of the anus and into the vagina of females. Although most frequent in boys and young persons, yet they are not uncommon at all more advanced ages, even in the most aged, in whom I have repeatedly found them the most tormenting. They are gregarious, forming balls in the large intestines, frequently along with other worms, especially the *Ascaris lumbricoides*. J. P. FRANK found them in the intestines of an infant so young that the umbilical portion of the cord had not separated. They are, of all the *Helminths*, the most frequent tormentors of every age and of every people; for they are not limited to particular parts of the world.

125. *c. Symptoms.*—These vary with the number of the worms and their position. A few hardly occasion any marked symptoms; but when numerous, in the lowest part of the rectum, they occasion extremely distressing itching and an irritating annoyance, difficult to be described, extending to adjoining parts. Certain articles of diet, as onions, carrots, fruits, &c., render the worms more restless and irritating during the whole day; but they are generally most annoying when the patient goes to bed. When the patient falls asleep, grinding of the teeth, excitement of the sexual organs, and restlessness are caused by them. The consequences of this local and constant irritation are, especially at, and subsequently to, the period of puberty, increased sexual irritation, masturbation, &c., in both sexes, and in the female sex most distressingly when

the worms wander into the vagina, when they occasion not merely pruritus, but also leucorrhœa, &c. The loss of rest and the irritation they produce ultimately impair nutrition, give rise to pallor, anæmia, and loss of flesh; irritation of the nostrils, sneezings, discoloration of the countenance, or a dark circle around the eyes, dilated pupils, and various sympathetic phenomena.

126. *d. The diagnosis*, however, of these thread worms can be established with certainty only by examining the fecal evacuations, especially after the administration of an enema. The *prognosis*, although the complaint is unattended by danger, is not favourable as respects either a speedy or a permanent cure.

127. *iii. STRONGYLUS\* and their Allies*.—This genus of worms has been often described; but, of the less recent writers, more especially by RUDOLPHI and BREMER. The species which most particularly interests the physician is,

128. *A. The Strongylus gigas*—*Ascaris visceralis aut renalis*, GMELIN; *Lumbrici renibus*, BLASIUS; *L. renalis*, REDI; *Fusaria visceralis aut renalis*, ZEDER. KÜCHENMEISTER remarks that BREMER has shown this worm, which occurs, although rarely in the abdominal cavity, the omentum, but especially in the kidneys and urinary bladder, more rarely in the lungs and liver, and only when strayed in the intestinal canal of martens, dogs, wolves, seals, otters, oxen, and horses, is still more rare in man; and that a number of those accounts of worms passing off through the urinary passages are delusions. Since a minute knowledge of the pathology of the kidneys has been acquired, it may be inferred that many of these cases would be recognised as fibrinous casts thrown off in the urine during disease of these organs. That these worms are extremely rare, even in the kidneys, must be admitted, since KÜCHENMEISTER has never met with a case in his own practice. He has, moreover, thrown rational doubts on the authenticity of most of the cases on record, showing that these cases, at least some of them, may have been instances of mistaken diagnosis. Dr. LAX-

\* "A. *Strongylus veri*. Corpore subcylindrico, utrinque attenuato; capite nudo raris alato, 2 appendicibus lateralibus armato; ore terminali, nudo vel sex papillis instructo, vel orbiculari; œsophago triangulari, muscicolo; cute tenui. Mas: appendices multilobata aut radiata; penis simplex vel duplex, multilobatus, ad digitum instar. Femina: cauda obtusa, recta; ano in parte caudali; vagina anterosum sita; utero simplici aut biloculati; oculis magnis (0.06–0.12 mill.). Animalia ovi- aut vivipara."—KÜCHENMEISTER.

DEJARDIN arranges the *Strongylus veri* as the xvth genus of his *Nematodes*. DIESSING places the two species, *Str. gigas* and *Str. longicaudatus*, in his Gen. liv., *Eu-strongylus*, thus defined by him: "Corpore subcylindrico, utrinque sensim attenuato, capite corpore continuo, ore terminali, orbiculari, papilloso; bursa maris terminali, integra; pene filiformi longo, haud vaginato; vagina anterosum aut retrorsum sita. Systemati ganglionum distinctissimo. Animalia ovi- aut vivipara, extra tubum intestinale habitantia."

† "Corpore rubro, cylindrico, longissimo, utrinque attenuato, atris aut annulis transversis interruptis et 8 fasciis fibrarum longitudinalium instructo; capite obtuso, truncato; ore orbiculari 6 papillis aut nodulis plurimis, appropinquatis; œsophago 15–22 mill. circiter longo, tenui et angustiore quam canalis intestinalis."

"Mas: corpore anterosum magis attenuato, 140 ad 140 mill.—10"—1" longo, 4–6 mill. lato; cauda obtusa cum bursa membracea patelliformi, circa 3 mill. latâ, truncatâ; pene tenuissimo simplici."

"Femina: corpore utrinque attenuato, 2 decim. ad 1 metr.=5"—3" longo, 5–12 mill. lato; cauda magis recta, obtuso-rotundatâ; ore triangulari, oblongo, sub extremitate caudali sito; vagina anterosum sita; utero simplici; oculis fere globosis."—KÜCHENMEISTER.

KESTER, however, states that there is a fine specimen of this worm taken from a human kidney in the Museum of the Royal College of Surgeons of England.

129. *a.* When fresh, this worm has a reddish colour. In spirit this colour fades, and the worm assumes a grayish leaden hue. Four longitudinal stripes are observed on it. The total length of a female specimen was 19 Saxon inches. DUBJARDIN states that the vagina opens 1 to 2 inches from the caudal extremity. DIESING says that the ganglial system of nerves is most manifest in this worm, a remark which is confirmed by BLANCHARD, OTTO, and VON SIEBOLD.

130. *b.* The symptoms of this worm are equivocal, for there can be no evidence of its existence to be relied upon until it is discharged, thereby demonstrating its existence. Another species of *Strongylus*, the *S. longecavignatus* of DIESING, has been said to have been found in the human subject, but without sufficient proof.

131. iv. *Ancylostomum*.<sup>\*</sup>—*Ancylostoma*, DUBINI; *Ancylostoma*, CREPLIN.—This worm was found by DUBINI in Milan, in 1838, in the duodenum and upper part of the jejunum; and subsequently also by PRUNER, BILHARZ, and GRIESINGER, in the countries watered by the Nile. According to VON SIEBOLD, it has never been found in Europe to the north of the Alps. DUBINI established this as a distinct genus from the *Strongylus*, by the symmetrical arrangement of the dental apparatus. We are, however, at present acquainted only with a single species of it.

132. *A. Ancylostomum Duodenale*.†—BILHARZ, having had his attention called to this worm by VON SIEBOLD, in consequence of PRUNER having found it in Egypt, observed it in every body he examined after death in that country, sometimes in small numbers, sometimes in hundreds, less in the duodenum than in the jejunum, between the transverse folds of the mucous membrane. One male is found to three females. At the oval end, a large, obliquely truncated horny capsule, furnished with four strong teeth on the projecting portion of the upper margin, is seen. The oval orifice is turned to the surface opposite to the

sexual and anal orifices. The animal attaches itself by its mouth so firmly to the mucous surface that the mouth is torn away when it is detached by force. Its nourishment is blood, as proved by its intestine being filled with this fluid.

133. *a. Pathology*.—This worm is of great interest and importance, and is often fatal to those afflicted with it. GRIESINGER, the best chemical observer of this worm, states that this worm attaches itself firmly by biting into the mucous and sub-mucous membranes; and that the spot on which a worm has been attached is indicated by an ecchymosis of the size of a lentil, in the centre of which a white spot the size of a pin's head appears, which is pierced by a hole penetrating into the sub-mucous tissue. From these wounds the blood enters freely into the intestine of the worm, which is filled with blood from the punctured places. Frequently the mucous membrane of the intestine is studded with flat, livid, brownish-red elevations of the size of a lentil. This is owing to the collection of the blood between the mucous membrane and muscular coat. In some cases a specimen of the worm is found lying in the cavity thus formed, covered with blood, with which it has completely engorged itself. The manifest consequence of this infestation is *anæmia*. GRIESINGER imputes the "*Egyptian chlorosis*," which he had previously described, and which, he avers, attacks one fourth of the population, entirely to the presence of this worm.

134. *b. Symptoms*.—At an early period, pallor of the face, general surface, lips and gums; palpitations of the heart, especially on any exertion, sounds in the jugular veins on auscultation, lassitude, debility without emaciation, are the chief phenomena. Subsequently disordered digestion, irregularity of the bowels, and *Catarrhus intestinalis* are complained of. These symptoms may continue an indefinite time; but if not removed by a decided treatment, the consequences are most serious, and generally fatal. Emaciation often does not commence until late in the disease. Edema of the extremities and eyelids; a pale yellowish or greenish yellow hue of the general surface; a withered, dry, flabby, and cold state of the integuments, and a remarkable pallor of the outlets of mucous canals; remarkable apathy, and sense of exhaustion; constant and distressing palpitations, the sounds of the heart being often heard at the distance of several feet; murmurs in all the larger arteries, and a rushing or purring sound in the jugulars, slowly supervene. The pulse is uncommonly quick and small; the respiratory movements are weak, frequent, and short; the urine is abundant, pale, and rarely contains albumen. Giddiness and headache are commonly experienced. Constant hunger, singular appetites, and slight febrile movements, sometimes with enlargement of the spleen and atrophy of the liver, are observed. With indulgence and full diet this state may last for years; but in very many cases the progress of the malady is rapid. Even in the best circumstances the patient is pallid, sickly, and miserable, exhibiting a high degree of *anæmia* and *hydræmia*. Various acute affections often supervene and complicate the disease, and a chronic diarrhœa or dysentery ultimately carries off the patient. Fatiguing labour, a lowering or antiphlogistic treatment, and debilitating agents hasten dissolution. A restorative regimen, change of climate, and

\* "*Termes subinervi, vivipari, corpus cylindricum; caput aequali attenuatum; pharynx infundibuliformis, colore subfuso, parietibus resistentibus. Longit. mar. 3—4''; fem. 4—5''; crassit. ad 1''.*" —DIESING et VON SIEBOLD.

judicious treatment, often arrest the complaint. All the phenomena consequent on the presence of these parasites are characteristic of a very slow but continued loss of blood, which, if not arrested, goes on until the quantity and the quality of this fluid are no longer sufficient to sustain life; death supervening with faintness, dyspnoea, and fatal syncope.

135. c. On examination after death, the organs and structures generally are wasted, pallid, and softened. The spleen is often enlarged; the liver is pale and atrophied; the veins are nearly empty; the heart and large venous trunks contain only soft, small brown coagula, with very little fibrin. In many even of the large venous trunks there is only a dark serous-looking fluid, with a few pale, large, and colourless blood-globules. The substance of the heart, especially the inner layers of muscles, are very pale and even fatty. This organ is generally large, thick, hypertrophied or dilated, particularly on the left side. The endocardium and valves are often irregular, as if thickened in parts. The brain, the lungs, the muscles, the digestive mucous surface, &c., exhibit remarkable pallor and anæmia; the cellular tissue and muscles being softened, flabby, and in parts exhibiting a watery infiltration (§ 134).

136. v. THE FILARIE.\*—These form the seventh genus of the first-class "Nematodes" of Dujardin, and the fortieth genus of the sixth order, "Nematoidea" of Diesing. From the *Gordii* they are distinguished by structure, mode of life, the nature of the youngest brood, and by the circumstance that they readily burst in water, like other *Nematoda*, which is not the case with the *Gordii* (Diesing).

137. A. *Filaria Medinensis*.†—PLUTARCH refers, in the ninth question of the eighth book of his "Symposiacon," to the statement of RHATHIARCHUS of Cnidus, the geographer and philosopher, "That the people on the Arabian side of the Red Sea suffered many strange diseases; among others, worms, like little snakes (*δρακόντια μικρά*), came out upon them, which gnawed their legs and arms, and when touched retracted themselves, coiled themselves up in the flesh, and gave rise to the most insupportable pains; but that this evil has been found only then, and nei-

ther before nor since among any other people." Many authors, with much appearance of justice, believe that the fiery serpents, which MOSES states to have been so destructive to the Israelites when journeying in the vicinity of the Red Sea, were *Filaria Medinenses*, and consequently that MOSES is the first writer to notice this worm, and that the fiery inflammation produced by it gave rise to the appellation bestowed upon it by the Hebrew writer.\* That the *Filaria* was considered a species of serpent by the ancients, is proved by the Greek name *δρακόντιον*, *dracunculus*, which was given it, and by the inflammation, pain, and swelling which occurred with the breaking out of the worm. The mortality among the Israelites may be explained by their ignorance of the proper treatment, and of the danger consequent upon the breaking of the worm. AVENZOAR states that, in his country, "Æger in continenti post dolorem vehementem in parte affecta exortum moriatur." The distemper being endemic in the place where the Israelites were sojourning (in Arabia Petrea), in circumstances of great difficulty and even distress, and during the hygienic privations of encampments in a barren country, it is not surprising that it then and there assumed an epidemic and fatal character.

138. SYNON.—The *Filaria Medinensis* has received a variety of names, viz., the *Dracunculus*; the *Drac. tibiarius*; the *Drac. Persarum*; the *Guinea-worm*, or *G. thread-worm*, from its frequent occurrence on the coast of Guinea; the *Guinea dragon*; the *Guinea hair-worm*; *Pharaoh's worm*; the *Skin-worm*; the *leg-worm*; *le Dragonneau*, *le ver de Guinée*, *le ver Cutané*, by the French; *Gumwischer Fadenwurm*; *Gumwische Drache*, *Pharaohswurm*, by the Germans.

139. a. Our knowledge of the natural history of this worm, and of the early stages of its development, is very deficient. KÜCHENMEISTER states that it is of the thickness of pack-thread, its anterior extremity obtuse, the mouth circular, without lips, but beset with four hooks, or more correctly with four styles, or acute straight spines; the vagina opens in the vicinity of the mouth, and the vagina and uterus are probably double, as in most *Filaria*. The length of the worm

\* Diagnosis: "Vermes albi, subfusci, aut rubri, corpore filiformi, elastico, cylindrico, ut plurimum longissimo; capite corpore continuo, inermi aut spinulis rectis et cornis (dentibus seu papillis prominentibus Autorum) armato; ore terminali non labiato, vel labiato rotundo, aut triangulari; œsophago brevi, tubuloso, rectiore quam intestinum; ano terminali aut ante caudæ apicem sito; cute levi aut leviter oblique striata.

"Mas: caudâ plerumque obtusâ, interdum membranâ accessoriâ aliam exhibente; spinulis filiformibus in vagina tubulosa aut ligulariformi, ex Dujardino inaequalibus, curvatis (?). Femina: vagina antorsum proximè ad os sita, plerumque duplici (*Filaria rigida* aut multiplici (ex. quinqueoculari in *Filaria labiata*, Nathusius); oculis ellipticis aut globosis, laceribus. Nunc ovi- nunc vivipara."

† "Mares omnino ignoti aut potius ab auctoribus neglecti et omissi, quin ob minorem magnitudinem minores efficiunt et molestias et dolores et vix unquam majores tumores; sed uti Diesingius ipse enarrat, a Clellandio in Calcutta Journ. Nat. Hist., l. 359, Pl. X., fig. 1, delineati.

"Femina: corpore longissimo (ad 3 ulnas et aliquid supra), subalbo, filiformi, subequali, secundum Dujardinum antorsum, sed secundum Diesingium et quidem quod ipse affirmare possum retrorsum, sensim attenuato, ad 1" seu ad 1—2½ null. lato; ore orbiculari, spinulis 4 cruciatim oppositis; ocellis ad apicem uncinatâ, subcutâ, in apice 0.065—0.068 mill.=0.025—0.036" Par.=0.029—0.037" l. latâ, interdum in vermibus ipsius cute ita affixâ, ut vix apicem liberum facere possis; vagina ovalis; embryonibus 1" longis, vix ½" latis. Species vivipara."—KÜCHENMEISTER.

\* Upon referring to a translation of the Bible from the Hebrew into Latin, with very copious annotations, by IMMANUEL TREMBELLI and FRANCIS JUNIUS (the former a learned Rabbi converted to Christianity, the first and second editions of which, published in London in 1679-80, and 1684, in quarto, are in my library), I find that he translates the Hebrew description as follows: "Tum inimisti Jehova in populum illum serpentes presteres, qui morderunt populum: ita moriatur populus multus ex Israele." Here TREMBELLI translates the Hebrew into venomous serpents; but in a note he states that according to the original they were fiery serpents. To this translation of the Bible and to its copious annotations, the translators of King James's Bible, and modern annotators, are more indebted than has been made to appear. Upon referring farther to the very rare edition of the Vulgate, also in my possession, which was printed in 1481, and known by the term "*Fontibus et Græcis*," &c., the serpents are called "fiery serpents (*Misit Deus ignitos serpentes*)—which inflicted wounds and death on many." This edition of the Bible is in folio, on a thick, beautiful paper, the ink being a bright jet-black, without the name of either printer or publisher, and without the verses being numbered, but with the Initial letters illuminated and coloured. These translations vary only in the term "venomous" being used by the former for "fiery," while the statement in the latter, that these serpents "inflicted wounds and death on many," may be considered as nearer the truth, as the infliction of wounds does not imply that death was always the result. Some translations, which retain the appellation "fiery," very justly explain it by stating it to refer entirely to the inflammation and pain produced by these animals.

varies from several inches to three yards. Statements of greater dimensions are probably founded in error. The whole surface of the worm and its tail exhibits the well-known fine rings, placed at a uniform distance. The substance of the body is homogeneous, finely granulated, and exhibits no traces of muscular fibres. Its œsophagus, intestinal canal, uterus, &c., require no description.\*

140. *b.* The worm is indigenous only in the hot zone, and, even when transported into colder climates, does not appear to propagate itself. Even in the hot zone it does not occur everywhere, but only in particular countries, like all the *Helmintha*, and is entirely in certain places in affected countries; as, for instance, in the Gambia, Angola, Canlabah, &c. The places in which the *Filaria Medinensis* more particularly occurs are Senegal and the coast of Guinea, the East Indies, Persia, Arabia Petrea, the coasts of the Red Sea, especially towards the south, the shores of the Ganges, Bombay, the Caspian Sea, Upper Egypt, Abyssinia, Nubia. It was introduced into America by negro slaves, especially into Surinam. Throughout the countries now mentioned it attacks aborigines and foreigners without distinction. According to PRUNER the worm often becomes epidemic, in wet seasons and in marshy districts. BREMER states that it is most frequently seen in the East Indies from November to January (the rainy season); and in Upper Egypt, according to BILHARZ, shortly after the inundations of the Nile.

141. *c.* The mode of production of the worm is still enveloped in obscurity. English officers, who never went about with the feet and arms uncovered, remained free from this worm. PRUNER thinks that the germ of the worm is an independent marsh animal, which is converted into a *Dracunculus* within the human body. FORBES believes that he found the brood of the *Dracunculus* free in the red, ochrey mud of the drying marshes. However, the aborigines think that it comes from the marshy grounds into the skin. The ordinary seat of the worm is the sub-cutaneous cellular tissue, especially of the lower extremities, around the ankle. It may, however, occur under the skin and muscles in all other parts of the human body. Instances of its occurrence in other parts of the body besides the extremities are recorded by KÄMPFER, BAJON, BAILLIE, PERÉ, and have been seen by myself in Africa. MCGREGOR, in 172 cases, states that it occurred 124 times in the feet, 33 times in the lower, 11 times in the upper part of the thigh, twice in the scrotum, and twice in the hands. PRUNER found a specimen behind the liver, between the layers of the mesentery. Sometimes the worm lies coiled up in a small space, sometimes it is extended; and in the latter case, if it lies on the surface, it feels as a varicose vein. PERÉ saw it lying in a snake-like form under the whole of the skin of the abdomen and a part of that of the chest, and similar cases of its extension are on record. "These examples will suffice to give a clear idea of this worm, of which, moreover, as many as twenty-eight, thirty, nay

even fifty specimens have been observed in one man." (KÜCHENMEISTER.)

142. *d. Diagnosis.*—If the worm is superficial, with a hard substratum, its growth is seen to take place with extraordinary rapidity, from 4" it becomes several inches long in a couple of days. It is then easily killed by poultices of boiled garlic, after which it is absorbed without injurious consequences. Frequently the worm occasions little or no annoyance for a long time. DAMPIER and ISERT had quitted the district of these worms for 6 to 8 months, and WENGLER's patient for 4 to 6 months before the worm betrayed itself. According to KÄMPFER and others, this latent state may continue 12 to 15 months, and in rare cases even until the third year. In other instances, emaciation, notwithstanding a good appetite and absence of fever, takes place, terminating at last in fatal exhaustion. When the worm is making its way out, a small pustule appears at the point where it will break through, sometimes with, and sometimes without, preliminary annoyance, or headache, pain in the stomach, nausea, fever, &c. At the point where it breaks through, inflammation, swelling, and suppuration occur several days previously, and continue until the worm is extracted. If it lies over or near to a joint, the use of the limb is prevented, and the symptoms are still more severe. In the case of DRUMMOND, after pain and stiffness of the leg, a reddish swelling, with a black point in the centre, was formed above the inside of the ankle; and at the same time he felt a firm, round, catgut-like substance twisted under the integuments. About three weeks after the first sensation of stiffness, he was seized with a sudden insupportable itching over the whole body, with fever, violent colic, vomiting, and purging; after which, shiverings without perspiration followed. In the mean time the swelling had burst, and a hard white substance appeared, but so deep that it could not be laid hold of, the animal having buried itself deeper among the muscles. The catgut-like twisted substance formerly felt was not now present. In the following night the ankle and vicinity were much inflamed; and three days afterward a thread was passed round the animal, and a bloody ichorous discharge continued for six or seven weeks from the wound, which healed up gradually to a small point, when the worm again came forth, and was fastened with a thread, rolled upon a stick, and drawn out twice a day. In twenty days the extraction was completed. Two or three days after the formation of vesicles on the inflamed part these open up, or are opened by a lancet, when matter, blood, and sanies, and two or three inches of the anterior end of the worm come forth. If this end be carefully pulled, several inches more often follow. All this is coiled around a little roll of linen or a small stick, and fastened over the wound with a compress and adhesive plaster; and the worm is thus wound out by repeated, careful operations, twice daily. The worm rarely comes away on the first attempt, several days, or even weeks, being required before this is accomplished. Mr. BUSK, in the *Transactions of the Microscopical Society*, has given one of the best descriptions of this worm.

[There are several species of *Filaria* not described by our author:

1. *Filaria Medinensis*, or Guinea-worm, above described. This is the most common and best

\* BREMER gives the following systematic description of this worm: "Longissima cylindrata, elastica, ferè equaliter crassa, capite attenuata, ore minime, circulari, cauda maris medium sui finis ad locum, quintali spirali, prominente, subulata, inflexa; femina semitereti, acutiuscula, incurva præstita: in hominis tela cellulosa subcutanea, præsertim pedum; in regionibus tropicis figi solita."

known species, being found chiefly in warm climates, where it is often seen in the morning dew, sometimes 10 or 12 feet long, and not thicker than a horse-hair. BACON states that he saw two instances where it had burrowed under the mucous membrane of the eyeball. As yet, only females have been observed in the human body—*viviparous*.

2. *Filaria Bronchialis*.—This species is described by TREUTLER, and so named from its occurrence in the lungs of persons labouring under phthisis. It has also been called *Hamularia lymphatica*; and by RUDOLPH, *Hamularia subcompressa*. This is also met with in the lungs of the inferior animals, especially when affected with tubercles. Dr. HOPKIN states that he often found the filaria in the lungs of the *boa constrictor*. They are usually about an inch long, roundish, blackish-brown, sometimes spotted white; and at one extremity, two projecting hooks. This species of filaria is probably allied to those worms which are not unfrequently found in the bronchi and lungs of animals belonging to the genus *Mustela*.

3. *Filaria Gracilis*, found in apes and monkeys in great abundance, grows to a length of 10 or 12 inches, about as thick as a fine thread, head obtuse, and tapering slightly at both extremities.

4. *Filaria Attenuata*, found in the abdominal cavity of crows, and in the cornea of the eye of fishes; from one to six inches long, and obtuse at both extremities.

5. *Filaria Obtusa*, inhabits the intestines of swallows; head somewhat acute, tail obtuse, body comparatively thick and elastic; has been found 12 inches in length. RUDOLPH has traced out its intestinal canal and ovaries.

6. *Filaria Truncata*, about 5 inches long, head truncated, tail somewhat thick, obtuse, terminated by a very sharp point; inhabits the larva or caterpillar of certain species of moths—(*Tinea padella*.)

7. *Filaria Ovale*.—This species went formerly under the name of *Gordius piscium* (hair-worm of fishes), because it is found in the liver of the carp, &c. It is 3 or 4 inches in length, head oval, tapering forward; tail round.

8. *Filaria Capsularis*; from half an inch to one inch long, and resembles in thickness a middle-sized thread. Borders of mouth recurved, tail obtuse, papilliform, ending with a sharp point. Often met with in the herring in large quantities; very tenacious of life, as it will live for many days in a dry place, and even revive after having been long frozen in masses of ice. This species has been formed into a genus by ZEDER, and other naturalists, under the name of *Capsularis*.

9. *Filaria Papillosa*.—The *Filaire cqui* of GMELIN, and the *Gordius equinus* of other writers—the species which inhabits the eye of the horse, from 1 to 7 inches in length, and one third of a line in diameter—of a yellowish-white or ash colour, sometimes of a brownish hue; head slightly obtuse; mouth orbicular; neck studded with papillæ; tail slender and curved. It occurs in different parts of the horse, chiefly in the muscles and intestinal canal, though it has been detected in the brain, as well as the aqueous humour of the eye. They often occur in the eyes of horses in the East Indies, as well as the muscles of the loins, causing paralysis. The Transactions of the American Philosophical Society, vol. ii., contains two communications on this subject, one by F. HOPKINSON, Esq., entitled "Account of a Worm

in a Horse's Eye;" the other by JOHN MORGAN, M.D., describing the same phenomenon. Similar cases will be found in the *Ed. Med. and Surg. Journ.* for June, 1826, and the *Bulletin des Sciences Medicales*, Feb., 1826. See, also, "An Account of a Filaria in a Horse's Eye, with Remarks on similar Phenomena, and the Mode of their Origin," with a plate, by C. A. LEE, in *Amer. Jour. of Science and Arts*, No. II., vol. xxxix.]

143. vi. ASCARIDES.—These worms are arranged by DUJARDIN as the nineteenth genus of the *Nematoda*; and by DIESING as the twentieth genus of the sixth order of the *Achathelmintha elastica*, but the *Oxyuri* are also introduced by him into this genus. The classification of DIESING is so involved that more confusion than elucidation is the result. Refining, hair-splitting, and drawing distinctions, which are either observed with difficulty, or not at all, are not the least faults of some modern observers. I subjoin DUJARDIN's systematic description of this genus.\* The only species to be here noticed is the,

144. *A. Ascaris Lumbricoides*.—SYNON.—*Ascaris gymnoascarida*, DIESING; *Ascaris lumbricoides*, LINNÆUS; *A. gigas*, GOEZE; *Lumbricus teres*, AUCT; *Fusaria lumbricoides*, ZEDER; but the Linnaean name is very generally retained.†

145. a. Description.—The head of the worm is distinctly composed of three papillæ, which can undoubtedly be spread out upon the intestine, in a broad, circular, sucker-like surface, in

\* "Ascarides: corpore albo aut subalbo, subcylindrico, utriusque attenuato, fusiformi, 4 strâs longitudinalibus subalbis, opacis, lineariibus, instructo; cute transverse striatâ; capite tilius, rufus (labris) convexis aut semilunariibus, interne fenestratis; œsophago valde musculosulo, cylindrico aut clavaiformi; ventriculo cavitatem triannularem præbente.

"Mas minor quam femina; extremitate caudali aliquid curvata, et involuta, nunc nudâ, nunc membrâ alidâ duplici, aut duplici tuberculorum et papillarum ordine aut rarissime acetalulo instructâ caudâ leviori, obtusiori, quam in feminis; spiculo aut pene duplice plus minusve longo et arcuato.

"Femina caudâ rectiore et longiore; vaginâ simplici anthorsum sitâ; utero bi-aut multiloculari; ovâs filiformibus, longissimis, duplicibus aut multiplicibus; ovula ellipctica aut globulosa, extus levia. Species aut ovâ viviparæ, plerumque in tubo intestinali riventes."

† "Utriusque aut rubro-pallidi, cylindrici, in extremitatibus attenuati, fusiformis elastici; cute transverse subarticulata strâs transversis 0.02 mill. inter se distinctibus, ex duobus stratis composita, 4 lineis lateraliibus longitudinalibus subalbis majoribus, capite distincto. parvo (0.7 mill. lato), tribus valvulis semilunariibus, prominentibus, ad margins hyaliniis armato, interne denticulatum musculorum strâum ad galli jubar modum præbente; œsophago musculosulo, 6—8 mill. longo, filiformi, triquetro, ventriculo clavaiformi (0.7 mill. lato, 2—3 mill. longo) parvulo, intestino simplici valvulis aut vilis et cythello polyedrico sparsim instructo.

"Mas: 15) ad 170 mill.—4 ad 6" longi. 3.2 mill. lat., caudâ aliquid depressa, conica, inflexa et curvata, spinulis 2 planis, subensiformibus, fere rectis, 1.8 mill. ad 2.12 mill. longis, 0.13 ad 0.23 mill. latis. Organo spermatico simplici, 1.200 mill. longo, testiculo cæco parvulo, retortiformi, fundo spermatico albo-intumido, ductu ejaculatorio angustiore ad aut latus sese aperienti. Spermatozoïda globuliformia, gramdosa, in femine vagina maturescunt.

"Femina: 200 ad 275 mill. et supra longa—8 ad 18"; media in parte 4 ad 5.5 mill. lata; caudâ conicâ obtusâ; aut aliquid ante caudâ apicem sito (1 mill. circiter); vaginâ simplici ante corporis dimidiam sitâ. ex magnitudine feminarum variabilis (ex c. 85 mill. pone caput in femina 245 mill. et 103 mill. in femina 214 mill. longa); utero ab initio simplici, bipartita aut biloculari. Ovaria filiformia, sensim attenuata, retrorsum usque ad anum, et anthorsum supra vaginam aliquantulum pergentia. Totâs utriusque ovarii longitudo ad 4" Lips.

"Ovula immatura subtriquetra, numero 4 ad 8 conglomerata, matra isolata, rotunda, ad 0.87 mill. lata, cum testâ tenui, levi; in natura libera sensim embryones evolventia."—KÜCHENMEISTER.

the sucking act of the worm. BREMSER has seen the opening and closing of these papillæ, and described the mechanism. He even reports that at the moment of opening he saw a little tube protrude from the centre, which is the true oral orifice. WEDL thinks that this is the cleft proboscis, which is everted from the oral aperture for the reception of nourishment. The true oral aperture is, however, formed by the opened lips or papillæ; the small tubule in the centre represents the *introtus faucium*. Its protrusion is probably as much by its own muscular structure as by the contraction of the general muscular structure of the body. The males and females may be distinguished by their form and external appearance. The abdomen of the female is slender, and fusiformly pointed. The male is bent like a hook, and sometimes presents, a short distance from the tail, a pair of white, delicate, projecting hairs, which are the protruded penis. If the female be pressed, or allowed to swell in water, a prolapsus of these tubes (ovaries), and a discharge of a milky substance (eggs), takes place in the anterior half of the animal from the vaginal orifice. If the male be pressed, a milky juice (seminal globules) flows out in the vicinity of the anus, without the occurrence of a prolapsus. The intestinal canal is whitish and muscular at its commencement; the œsophagus is composed of thick layers of longitudinal and transverse fibres, and passes rapidly, and without any marked constriction, into the intestinal canal, the parietes of which are thin, internally covered with epithelium, and shines through, of a brownish colour, from the brown excrement. This intestine has a muscular coat, which is connected with the cutaneous longitudinal and circular muscles. The external integument consists of six layers. Under the outer layer are two layers of fibres crossing each other obliquely, and two laid at a right angle over each other, and between the former and latter two a sixth homogeneous layer, which appears to contain a peculiar odoriferous fluid of an oily and reddish appearance, and exhibits refractive phenomena (KÜCHENMEISTER).

116. *b. Symptoms.*—Very generally the host and his guests, the *Ascarides*, agree very well together, until, owing to causes affecting these animals, or the digestive organs of their host, a disagreement between them takes place, and various disorders or symptoms ensue. When these worms are few in number, notwithstanding their size, they often occasion but little disorder, and live amicably with their entertainer on unelaborated chyme, until their numbers, changes of diet, and other occurrences produce more or less ailment. In most cases, when their numbers are not great, a good, or a too good appetite, is the chief injury they do; and in this respect they are much less noxious than the much smaller *Ancylostoma*. Great numbers of these worms in the intestines, and a firm aggregation of them into coils and knots, sometimes with the small threadworms intervening, often occasion much disorder, according to the mechanical obstacle and the irritation they may produce. Colic, ileus, constipation, diarrhœa, flatulency, congestions of the brain, especially in children, and various reflex phenomena manifested in distant parts, and on voluntary muscles both of the trunk and of the lower extremities, are then not unfrequent occurrences. Besides the influence of inordinate numbers—of 200 to 350—knotted into balls,

which I have expelled from the bowels of both children and adults, the irritation and the consequent effects produced by even small or moderate numbers are often serious; for, owing to states of the digestive organs of their host, to the influence of certain kinds of food, or of change of diet upon them, or to the agitation arising in them from the influence of season, and to the periodical seeking of the females by the males, much disturbance may ensue, or the worms may travel or stray into parts of the digestive canal not usually visited by them, and thus induce very serious effects, which may even terminate in death. These effects, however, will depend much upon the irritability and other circumstances of the patient, the number of the wanderers, and the parts which they have reached. When irritations of the intestinal canal occur, and produce watery diarrhœa, cholera, &c., these worms are thereby affected; they swell up, lose their powers of adhesion, and are often carried away *per anum*. But one or more worms may pass unusually high in the intestines, may rise through the pylorus into the stomach, and occasion retching, vomitings, &c., irritation in the œsophagus, fever, delirium, and upon the discharge of the worm all rapidly disappear. But before rising so high in the digestive canal, one or more may pass into the common duct, or even into the cystic, or the hepatic, or the pancreatic ducts, and produce symptoms similar or approaching to gall-stones, or inflammation, spasm, and disease of these ducts. These latter occurrences are, however, very rare; for generally the secretions passing along these ducts into the duodenum are not much relished by these worms, and these routes are not pursued by them. When the worm passes into the stomach, it may rapidly rise into the upper part of the œsophagus or into the pharynx, and even get entangled in the larynx and produce the most distressing effects. But such occurrences, although observed, are very rare. After long periods of abstinence or inanition they have been found to migrate and escape from the anus, mouth, and nose; and such migrations are not uncommon in the course of continued and remittent fevers.

147. The *symptoms* produced by *Ascarides*, while they continue in the intestine, are mechanical, direct, and reflex. The former are the phenomena of the usual catarrhal affections of the stomach and intestines (gastro-intestinal irritations) in every grade; costiveness, tormina, colic; a sense of weight, of irritation, or of a ball, or gnawing and itching near the umbilicus; disordered, craving, and irregular appetite, and digestion, &c. The latter are hiccup, subsultus of the abdominal muscles, cramps of the lower extremities, yawning, increased secretion of saliva, snuffling or tickling of the nose, but rare of the anus, unless upon the passage of a worm.

148. The question has been often entertained as to the possibility of these worms perforating the parietes of the healthy intestines, and making their way into places more or less distant from their usual residence. That these worms can never perforate the healthy intestine, the structure of its head and its thin lips being adapted only for suction and not for boring, is the opinion of RUDOLPHI, BREMSER, ROKITANSKY, BEMBERGER, J. P. FRANK, KÜCHENMEISTER, and myself, in opposition to that of VON SIEBOLD and MONDIÈRE. Therefore it may be concluded that when these

worms are found in situations external to the digestive canal, they have reached it by some pre-existing ulceration, perforation, or fistula.

149. Many, especially of the older authors, have attributed a prognostic and generally an unfavourable import to the discharge of worms during febrile diseases, and more especially during typhoid fevers; and this opinion is not limited to the Ascarides, but is extended to the flat worms, and they have argued that the worms in these circumstances are like the rats, and have the presence of deserting a sinking ship! But as the discharge of worms from a fever-patient does not occur until after the seventh day, according to ZIMMERMANN, it is much more probable that they travel from the intestines, owing to the food obtained by them being insufficient or not suited to them, and to the secretions of the intestines being injurious to them, and in search of more abundant or more suitable aliment. The ulcerations of the intestines and the morbid matter from these ulcers in the advanced stages of continued fevers, will also tend to expel or to occasion a discharge of these worms, which, when observed, may be justly viewed, both as an indication of the existence of these lesions and of the extreme danger of the malady.

150. VI. A GENERAL VIEW OF THE SYMPTOMS PRODUCED BY WORMS IN THE DIGESTIVE CANAL.—Most of the symptoms produced by worms may arise from other causes; but a careful recognition and observation of these symptoms, of their successions, grouping, &c., are requisite for the due regulation of the treatment, and for the ascertaining of the species of worm which is present. The symptoms produced most commonly by the individual species of worm have been noticed with reference to each; but recent writers have been more intent upon the microscopic descriptions of these parasites, and upon drawing minute distinctions, &c., than upon more useful and practical considerations connected with them. It is justly argued that the discharge of the more common species of worms infesting the intestinal canal is the only true *diagnosis* of verminous diseases; but this discharge, even in the most serious cases, may not occur without means being used to effect it; and it is by a knowledge of these symptoms, independently of such discharge, that we are led to administer the means most likely both to establish this diagnosis and to effect a cure.

151. A. The more direct and local symptoms, or those more immediately caused by worms, are—a capricious and variable appetite—at one time a craving and insatiable hunger or an unsated desire of food; at other times, nausea, or cardialgia, borborygmi, loathing, retching, or vomiting, being present; a sense of weight in the abdomen, with distention, gnawing, or erosion; a feeling of cold internally, or of emptiness or inanition, often with palpitations, or leipothymia, or faintness; a dragging, twisting, or lancinating pain in the abdominal regions, especially near the umbilicus, or tormina, spasms, colicky attacks, tenesmus, constipation, or irregularities of the intestinal functions; leucorrhœa, and itching, or a mucous or watery exudation from the anus, sometimes a mucous diarrhœa, tenesmus, and bearing down pains in adult females, or derangements of the catamenia, or even abortion; and in children more especially tormina, colic, constipation, and intus-susception of the bowels, with various cerebral symptoms

about to be noticed. In both sexes “manustupratio” is not unfrequent, even at an early age.

152. B. The symptoms caused in more distant parts by sympathy with the seat of irritation, or by direct and reflex sympathy, are chiefly a frequent, dry, and tickling cough; hiccough, anxiety at the præcordia, or pungent pains passing under the false ribs and at the epigastrium; a sense of something in the œsophagus, sometimes with tickling in the pharynx; partial amaurosis and dilatation of the pupils; sneezings, itching and dryness of the nose and nostrils, sometimes epistaxis, itching of the skin, without eruption; grinding or grating of the teeth, and sudden startings when asleep; subsultus and spasms of the abdominal muscles; partial or general convulsive movements without complete loss of consciousness; chorea or twitchings, or irregular contractions of particular muscles, especially those of the face and lower extremities; and more or less fully developed, general, or epileptic convulsions. The urinary excretion is sometimes disordered, and dysuria or frequent micturition complained of, the urine being whey-coloured, turbid, &c., with or without a sediment.

153. C. A general verminous cachexia is not unfrequently present, manifested by a pale, tumid, or livid state of the features; by a sunken appearance of the eyes and a leaden hue beneath them; a general pallor, and more or less anæmia of the surface of the body, lips, &c.; a perverted state of the sense of smell, or the entire loss of smell; a strawberry hue of the tongue, or mucous sordes on the tongue, and about the teeth and gums, stridor of the teeth, and a peculiar fœtor of the breath, sometimes a more or less evident affection of the voice and speech; a morose, irritable state of temper, vertigo, frightful dreams, timidity, somnolency; slight or low delirium, risus sardonius, and prostration of strength. The biliary secretion is sometimes scanty, and in some cases even jaundice is observed. The abdominal secretions are very often disordered, and the functions of excretion generally impeded. These and other effects—local and sympathetic—are manifestly produced: 1st, by the irritation of the digestive mucous surface, which may, in the cases of certain worms, and in susceptible constitutions especially, go on to inflammation and its consequences; and, 2d, by the changes these animals produce in the chyme and chyle derived from the ordinary food, and upon the secretions of the gastro-intestinal surface, and upon those of the liver and pancreas. The former of these effects, namely, those consisting of gastro-intestinal irritation and its consequences, will also contribute to the production of the latter; but it cannot be doubted that much of the nourishment which should be taken up by the intestinal surface is intercepted by these parasites, while a portion of the fluids, lacteal or serous, are removed from this surface by the suction exerted by these animals.

154. All the symptoms now enumerated are not observed in the same case, but many of them either coexist or appear in succession, and are variously grouped in different subjects, so as to render a diagnosis very difficult between this and other complaints. When the cachexia, debility, and sympathetic disturbance of the brain and its functions are considerable, more especially when the circulating fluids are diminished in quantity from deficient aliment, or impaired in quality by

imperfect assimilation and depuration, the symptoms may assume a febrile character, sometimes mistaken for a form either of low fever, or of gastric fever, but more correctly recognised by some of the older writers by the term worm or verminous fever. (See also § 73.)

155. vii. THE CAUSES OF WORMS may be inferred from what has been stated above; yet it may be of use to notice some particulars too generally overlooked by the recent writers, who have insisted upon the propagation of worms by means of ova, &c., and who may be considered as having disproved the doctrine of equivocal generation, or, more correctly, of spontaneous formation. A knowledge of the *predisposing causes* furnishes important indications in both the prevention and the treatment of verminous diseases; for, although the obsolete doctrine of spontaneous formation rendered this knowledge of the greatest interest, inasmuch as it was founded upon antecedent changes in the constitution, yet these changes are by no means devoid of influence in favouring the development of the ova and embryos of parasitic animals. There can be no doubt that children of weak, aged, and vitally exhausted parents; the female sex, debilitated males; and persons of all ages, who have been insufficiently or improperly fed in early life, or of a relaxed fibre or asthenic diathesis, are much more subject to worms than those who are otherwise circumstanced. A tender and delicate state of health in early life; the use of crude, viscous, gelatinous, and vegetable food; whatever tends to lower the organic nervous force and vital resistance; a relaxed and asthenic habit of body; hereditary conformation; a residence in crowded and insufficiently drained cities and towns, or in cold and moist situations, especially in those which are abundantly covered with vegetable productions peculiar to the country, and a scanty use of such condiments, as salt and hot spices, as the climate may require, predispose to the generation of worms. In places where salt cannot be obtained in quantities requisite to the wants of the economy, as in some intertropical countries, the hot spices are used in its place by the natives. Those who contend, and, from recent researches, with manifest truth, that the presence of ova is necessary to the generation of human parasites, consider that the predisposition produced by these causes favour this generation, and that robust health and a sound constitution are subversive of their development. Those who argue for their spontaneous formation believe that these causes not merely predispose to this formation, but also directly produce it; and that, owing to a weak and imperfect chylification and assimilation, or to a metamorphosis of the secretions, a material is evolved which, under the favourable circumstances in which it is placed, and owing to a vital emanation from the body in which it lodged, assumes an organized and separate existence. These doctrines, however opposite—the former assuming, as predisposing causes, merely what the latter contends to be direct and exciting, or efficient, causes—agree in that which is of the greatest importance to the physician: they both point out the best indications for preventing the continued or the future generation of worms, where they already exist or have existed, and for guarding against their invasion in circumstances which render such invasion more or less probable.

156. IV. TREATMENT OF WORMS.—The treatment of worms should have reference, 1st. To their *prophylaxis*, or prevention; 2d. To their *expulsion*; and, 3d. To the *prevention of their recurrence*.

157. i. PROPHYLAXIS.—A. As to the *first of these intentions*, it must be admitted that the accomplishment of it is always difficult, and often impossible. Our knowledge, also, of the modes and channels by which these parasites are conveyed into and propagated by the lower animals and human subjects is imperfect. Admitting that they originate in ova which experience the changes in the processes of their development above described, we still find it difficult to account for the presence of these ova, and for their passage into the human stomach. That the ova, as stated above, may attach themselves to raw vegetables and fruit, is not improbable. The feeding of domestic animals also upon the garbage or viscera of fish, fowls, or the mammalia, certainly favours the production of worms, especially those of the cistoid order, in these animals; and the ova from these, where perfect cleanliness in all respects is not observed, may be conveyed in the food or drink, or by the hands, especially unclean hands, into the human body. The amount of knowledge as to this topic appears to be limited to the observance of perfect cleanliness in all its bearings, including the utmost care as to the purity of the water used, and as to the use of raw vegetables and fruits. Marsh, stagnant, and even river water ought not to be used; or if the latter be taken, it ought to be previously boiled or filtered. Vegetables and fruits should be carefully washed, especially fallen fruit, if eaten in a raw state; and the domestic animals ought to be confined to their proper places, and neither petted nor fondled. The diet is also of some consequence; and no kind of animal food should be taken unless it be sufficiently cooked. The raw flesh of animals, especially of pigs, and imperfectly cooked viscera of animals, and all unnatural modes of living, and neglect of the strictest attention to cleanliness in respect of diet and modes of living, should be most carefully avoided.

158. B. But it is not only the *prevention of the ingestion of ova* into the human body that should be studied, but also the *means of rendering these ova inert, or rather of preventing their development* in the digestive canal. As with the former, so with the latter means of prevention, our knowledge is very imperfect. We may, however, infer that those *predisposing* causes of worms enumerated above should, as much as possible, be removed or counteracted. Without a due attention to the removal of the predisposition, which favours the generation and development of the entozoa; the treatment of verminous diseases will prove inefficient as regards the issue, and empirical in practice, especially when viewed in relation to the scientific application of the resources which the progress of knowledge and the discoveries of our contemporaries have placed within our reach. In furtherance of this indication, the diet and the treatment should be adopted that are most efficacious in promoting the organic nervous force, and the tone of the digestive organs, and in removing tenacious mucus and pituitous sordes, which often adhere to the digestive mucous surface, especially in asthenic, leucophlegmatic, and debilitated subjects, and

which often form the nidus in which the ova of parasites are lodged and hatched. It will generally be noticed that the secretions and excretions, which in all persons form the principal part of the fecal discharge, are seldom thrown off from the secreting surfaces so quickly and entirely in the delicate and debilitated as in the robust and healthy; but remain or are retained in the former class of subjects, and become the soil in which these animals are reared.

159. C. Persons who are, or who have been, subject to verminous diseases, ought to adopt that kind of food, and to have recourse to those medicines which their feelings and observation indicate as being calculated to distress, injure, and ultimately to destroy or eject intestinal worms. A due attention to such means is required not only for the expulsion, but also for preventing the future generation of these parasites. Another object, and one, indeed, which is the basis of the prevention and of the treatment of worms, is to determine in as accurate a manner as possible, from the character of the symptoms, and from the examination of the feces, the species of the animal which is to be dislodged. While, however, this diagnosis receives its due attention, care must be taken not to mistake other diseases, which possess many of the same features, for those proceeding from the presence of worms. This error is likely to occur frequently, since the one class of disorders often reciprocally bear the relation of cause and effect to each other. Nor, in many cases, will it be attended by any serious consequences, farther than from wanting appropriate direction, the treatment must be inefficient, and redundant and superfluous. It should also be kept in recollection that worms are more apt to be generated during fevers, and during convalescence from fevers, especially such as are epidemic, adynamic, or nervous, or are gastric or exanthematous, than in robust health, or even in other circumstances. The generation of parasitical animals in these maladies is not confined to the surface of the intestinal canal only. It is not unusual to observe the parasites usually produced, in favourable circumstances, on the external surface of the body, become remarkably abundant during and after these fevers, especially when the diseased secretions are allowed to accumulate from a neglect of ablutions and of frequent change of linen. The appearance of animal parasites on these occasions was explained by the supporters of spontaneous formation, in the way above noticed (§ 6, *et seq.*); while it was viewed, by the believers in generation from ova, as the result of a more favourable occasion being furnished for the development of the ova during these diseases.

160. One of the earliest methods of preventing and of curing verminous diseases, resorted to by many physicians, is to remove or attempt to remove, by purgatives or drastic means, the tenacious mucus adhering to the digestive mucous surface, and which, as they believe, forms the nidus or lodgment of worms; and they believe that the quantities of mucus dislodged from the bowels during and for some time after the exhibition of vermifuge, and other purgatives, are proofs of the accumulation of this mucus on the intestinal surface. That this mucus or sordes may be excessive in many cases, may be admitted; but it may also be allowed that the greater portion of this mucus is produced by

the irritation of the intestinal mucous membrane by these purgatives. This method of prevention and treatment, when moderately and appropriately prescribed, may be of service in many cases, but it should not be overlooked that the rough operation of these medicines often leaves a debilitated state of the intestines after their operation, which disposes them to generate, and prevents them from throwing off the mucous sordes and worms which these medicines were employed to remove. They cannot by any mechanical property, or by any chemical or other influence on the intestinal secretions and excretions, always remove them from the extended surface covered by them in the manner or so completely as contemplated; and, even when the proposed end is completely attained, the intestinal functions are left in a more favourable condition than before, to reproduce both mucous sordes and worms, especially if any of the ova still remain unexpelled. Therefore, instead of trusting to the medicines usually employed as anthelmintics, vermifuge purgatives, alterants, &c., our attention ought to be directed (in some cases instead of these medicines, in others in addition to them, and subsequently to the use of them) to the adoption of remedies which promote the organic nervous forces, and the digestive and vital energies in general, thereby increasing the healthy and vigorous discharge of the various functions, and the due evolution and evacuation of the secretions and excretions from the digestive organs. (*See also the treatment after the expulsion of worms.*)

161. ii. DIRECT AND CURATIVE TREATMENT — J. P. FRANK, whose experience of the treatment of worms, when he wrote on the subject, had extended to half a century, considered that drastic purgatives and anthelmintics at the commencement of the treatment were seldom so serviceable, especially against tænia, as more gentle measures, which, in his opinion, should be first adopted, and be followed by more energetic remedies. But the diversity not only of these medicines, and of the combinations and methods of prescribing them, bewilder the inexperienced, until repeated opportunities of observation enable him to select those means and combinations upon which confidence can be placed. KÜCHENMEISTER justly remarks that, if the multitude of remedies recommended for any disease is an evidence of their want of power against it, the therapeutics of worms are extremely defective. In truth, the treatment of these parasites leaves much to be desired as respects the efficacy of the medicines prescribed for them, the pleasantness of the most efficacious among them, and the disagreeable effects which often accompany and follow those most to be relied upon.

162. A. THE TREATMENT OF TAPE-WORM will firstly, and more especially, occupy attention, as it will comprise the most efficacious medicines and methods which have been employed, not only for these worms, but also for many of the others which have been noticed above; and when the treatment of these latter comes under consideration, then a brief reference to what has already been stated will be sufficient. KÜCHENMEISTER tested a great many of the medicines recommended against tænia, by placing live tape-worms in a mixture of the particular medicines with white of egg, and by determining the time in which they died by the assistance of the rotation apparatus, the two poles of which he introduced into

the mixture. According to these experiments, the *tenia* lived for many hours, or even for days, in the mixture containing the *cuprum oxydatum nigrum*, in that containing *dolichos pruriens*; and for several hours in *castor-oil*, and in a salad made with *pickled herrings*, *onions*, *garlic*, &c. Tin has little or no effect, or merely the same effect as the cow-itch. Electricity has no destructive action on *Tenia*. "It is otherwise, however, with *koussou*, in the infusion of which, mixed with milk, the *tenia* died within half an hour of their introduction; and with *oil of turpentine*, in a mixture of which with white of egg, they died in 1 to 1½ hour. In a decoction of *Brucra* (*koussou*) mixed with white of egg, the *Tenia* died in 1½ to 3 hours. In a decoction of *rad. punice granatorum*, mixed with white of egg, in 3 hours; and with the same decoction, mixed with milk, in 3 to 3½ hours. In a mixture of *extract. filicis maris æther.* with white of egg, the *Tenia* died in 3½ to 4 hours. The so-called *filicine* (*filicie acul* of Lutz), mixed with white of egg, also has an energetic action on the *Tenia*, which die therein in the course of a few hours, and exhibit œdematous swellings in various parts." The particular methods of expulsion, arranged according to the remedies, have been enumerated by MEYER, SEEGER, and KÜCHENMEISTER; but the faults which this last-named writer finds with his two predecessors, viz., that in the enumeration of methods these are thrown together in a disorderly manner, may also be imputed to himself, although in a less degree.

163. *a* METHODS WITH TIN.—FRANK commences the treatment with the powder of *tin*, or its filings, given in a simple sirup, either alone or with *sulphur*, or the *extractum absinthii*. After having pursued this plan during three or four days, allowing only a spare diet, he prescribes, in addition to the tin, a moderate dose of *jalap*, low diet being still observed. DUPUIS prescribes, without any preliminary treatment, at six and at half-past six in the morning, each time a powder of *Stann. rasp. Angl.*, ʒss.; *Tannini puri*, ʒi.; *Giguthi* (*cambogæ*), gr. vi.; *Elæosacchari cajuputi*, gr. ijss.; and after each dose the patient drinks two cups of black coffee. In two hours the worm is expected to pass off, usually with colicky pains, on the occurrence of which strong black coffee is immediately given. For the subsequent treatment, a tincture of iron is advised. BECKER recommends the chemically precipitated *tin*. According to him, it is certain in its action, does not irritate the intestines mechanically, and is preferable in doubtful cases. It is, however, difficult to be obtained. KÜCHENMEISTER protests against the administration of tin-filings, as being, in his opinion, a much too irritating medicine. But he has twice prescribed *tin*, precipitated from chloride of tin, in an extremely fine powder, making it into an *electuary with honey*, a little *extr. punice granat.*, *extr. filicis maris æther.*, and *camboe* or *jalap*. Even young and weakly children support this remedy very well. On one occasion the entire worm passed, dead, on the second day. In the other case, an adult, several yards passed after this medicine, but the remainder of the worm was expelled by his ordinary mixture (§ 181). He considers the medicine to be uncertain, but suitable to children and persons who are much reduced. Tin, in various combinations, has been prescribed, also, by ALSTON, MAYER, MATTHIEU, HAUTESIARK, and AU-

TENRIETH; but its operation, as they have prescribed it, is often either ineffective, or too irritating to the digestive mucous surface.

164. *b* METHODS WITH THE MALE FERN.—The *Aspidium filix mas*, which is always efficacious against the *Bothriocephali*, is much less so against *Tenia*. BUCHHEIM prescribes a soft resin, obtained from this plant, with good effects. The most efficacious preparation, according to KÜCHENMEISTER, is the *æthereal extract of Filix Mas*, the powder being mixed with the extract, so as to increase the surface of contact of the medicine; or the extract being mixed with pomegranate root, which latter he prefers.—(a) WAWRUCH's method is a *preliminary treatment* of three to four days, consisting of strong beef-tea with white bread, three times a day, taking at the same time the following resolvent: *R. Rad. taraxaci et cichoræ*, ʒā, ʒj.; *decoque per ½ horæ: colaturæ* ʒvj., *adde ammon. chlor. præcip.*, ʒj.; *syrup. cichoræ cum rhco*, ʒss. M. Two table-spoonfuls every two hours. With this, daily laxative clysters of milk, linseed, herb. althææ, flor. verbasc., and flor. papaver. are ordered, and on the evening before the expulsion, a very rich gruel (½ lb. of water, and 2 to 4 ounces of butter and wheat bread). The *expulsion* is attempted by taking, "in the morning, fasting, a thick gruel; and about five, six, and seven o'clock a clyster of linseed and milk; about eight o'clock, two table-spoonfuls of castor-oil; at half past eight, pulv. rad. filicis maris ʒij.—Div.; at nine o'clock, two table-spoonfuls of castor-oil; at half past nine, the fern-powder again; at ten o'clock, two table-spoonfuls of castor-oil; and at half past ten, the third powder. After each dose the patient washes his mouth with tea made from flor. tilia, and summit. millefolii; and in the intervals he chews flavid. cort. aurantior., of which a dose of ʒss. is prescribed. At one o'clock he takes a powder of camboe and calomel, ʒā, gr. v.—vj., with ʒss. sacch. albi, and applies emollient poultices over the abdomen. If the worm be not expelled, castor-oil is again given in half an hour; in a second half hour, camboe powder; then castor-oil again; and possibly, if no inflammation occurs, the powder of camboe and calomel again at half past four. At the same time, a clyster is administered every hour!" The subsequent treatment consists of the removal of the inflammatory state of the intestines by leeches, mild diet, &c.

165. (*b*) *Weisshaar's method* is a modification of the above. On the second, third, and fourth day of *preliminary treatment*, a pickled herring diet; and on the following day he attempts the *expulsion* of the worm nearly as advised by WAWRUCH, excepting that he gives the castor-oil in meat broth, and, instead of orange-peel, candied calamus. Of the fern-powder he gives only xv.—xx. gr. *pro dosi*, with 15 to 20 grs. olei filicis maris; and even the latter only to irritable subjects. Recently he prescribes 60 to 80 drops ol. filicis maris with ʒss. ol. ricini; in half an hour, two table-spoonfuls of castor-oil; in an hour, the first powder of camboe and calomel; in half an hour, oil again; in another half hour, the second powder of camboe and calomel, and so forth. He states that he easily expels *T. solium* by this method; but that *T. medioancillata* (§ 68 to 70) requires strong doses of oil of turpentine.

166. (*c*) The *Wurtemberg method* is one ounce of fern-root boiled for an hour with three pints of

water; one drachm of fresh *cort. mezerei* is added to the hot decoction, which in ten or twelve minutes is strained, and then mixed with two or three drachms of finely-powdered fern-root. This is taken in the morning fasting, either at once, or in three portions at intervals of an hour. In three or four hours sickness and disorder of the stomach cease; and then calomel, freshly prepared sulphate of iron, *aa*, gr. x.— $\mathfrak{z}$ j., according to age, are administered, and repeated if vomiting occur. The worm is said to be generally expelled in the evening; when this is not the case, a rich gruel is given on the same evening; and on the following morning, fasting, rhubarb and jalap, *aa*, gr. x.—xv.— $\mathfrak{z}$ ss.

167. (d) *Alibert's and Dubois' methods* are nearly the same, and as follows: After a preliminary treatment for eight days, to which garlic, roasted under the ashes, is added, the abdomen is to be rubbed several times a day with a liniment of camphor, with balsams and nut-oil, and with crushed bulbs of garlic, also a pisan of *helminthocorton* and *filix mas*, and a nightly enema of marsh-mallow water are prescribed. Without this preparation, ALIBERT prescribes,

No. 330. R Rad. Filicis Maris,  $\mathfrak{z}$ iv.; Coque cum Aq. Font., lb ij., usque ad remanentiam lb ij.; Colature adde Syrupi Helminthocort.  $\mathfrak{z}$ j. M.

This is to be drunk in cupfuls during the day. After three hours of repose, calomel and corn. cerv. ust., of each gr. ij., made into a bolus with conserv. rosæ q. s., are given. In the evening,  $\mathfrak{z}$ j. of oil of sweet almonds; and on the second day the following purgative:

No. 331. R Scammonii, gr. xvij.; Rad. Filicis Maris,  $\mathfrak{z}$ j.; Cambogiæ, Calomel., *aa*, gr. xij. M.

To be taken in three portions in sugar and water. DUBOIS, after the preliminary treatment just noticed, prescribes, early in the morning,  $\mathfrak{z}$ ss. of *filix mas* in broth; and every half hour one of the following:

No. 332. R Res. Jalap., Scammonii, Cambogiæ, *aa*,  $\mathfrak{z}$ ss.; Syrupi I.hamnii Cathart., q. s., ut fiant boli, sing. gr. vj.

168. (c) *Bichung's and Seeger's Methods*.—The former commences with draughts and clysters of cold water, and with full diet and cold baths. With this diet, but without the cold water, according to SEEGER, a saturated decoction of  $\mathfrak{z}$ ss. of fern-root is drunk cold after every meal, when the worm will be expelled in from three to fourteen days. SEEGER's plan, according to KÜCHENMEISTER, is suited to irritable and weak persons.

169. (f) *Nuffer's and Odier's Method*.—The evening before the treatment the patient takes a thin gruel with two ounces of butter; a quarter of an hour afterward, a glass of wine, and, if necessary, a clyster. The next morning, fasting,  $\mathfrak{z}$ ij. pulv. fil. maris in  $\mathfrak{z}$ iv.— $\mathfrak{z}$ vj. aq. tilis. If vomiting occur, this is to be repeated; and if sickness be felt, black coffee is taken. Two hours after this the following bolus is given:

No. 333. R Calomel., Scammonii, *aa*, gr. x.—xv.; Cambogiæ, gr. v.—vij.—viij.; Confect. Hyacinth., q. s. Misco.

For weak patients and children, in two doses. If the bolus be thrown up, or not have operated in four hours, or if the worm hangs out of the anus,  $\mathfrak{z}$ vj.— $\mathfrak{z}$ j. of Epsom salts, dissolved in warm water, are given. If the worm be not expelled by this, the gruel and powder are to be repeated, but the Epsom salts are to be given instead of the bolus. ODIER directs a table-spoonful of castor-oil in meat broth every half hour instead

of the bolus. This treatment is said to be certain against *Bothriocephali*.

170. (g) *Blossfeld's and Rapp's method* is much praised. The previous evening a thick mixture of bread and milk is taken; and in the following morning  $\mathfrak{z}$ j. pulv. rad. fil. maris is given every hour, in an ounce and a half of nutmeg tea. After six or eight doses the worm is expelled. RAPP directs the root to be fresh, and administers  $\mathfrak{z}$ vj.— $\mathfrak{z}$ j. of it one dose.

171. (h) *Mayor's Method*.—MAYOR, of Geneva, regards the root of *filix mas* as specific against *Bothriocephalus*, and tin and pomegranate root against *Tenia solium*, and states that the powder of the fern-root should appear quite green, as it is otherwise inefficacious. He gives  $\mathfrak{z}$ ij.— $\mathfrak{z}$ iv. in a mixture of balm tea and  $\mathfrak{z}$ j. of gum sirup. This draught is to be taken at night, and  $\mathfrak{z}$ jss. of castor-oil the next morning. MAYOR, in some cases, instead of the powder, prescribes the *oleum filicis maris* in the form of pills—thirty to fifty drops in twenty-four pills, of which twelve are taken at night and twelve in the morning, and an hour afterward  $\mathfrak{z}$ jss. of castor-oil. In other cases he gives the fern-oil, either pure or mixed with castor-oil, in doses of  $\mathfrak{z}$ ss.— $\mathfrak{z}$ j.; but usually the castor-oil afterward.

172. (i) *O. Bang's Method*.—"For three days the patient takes only one basin of meat broth, with white bread. At night he has a clyster of warm milk. On the fourth day he takes also eight cups of black coffee with plenty of sugar, and two to three large pickled herrings in the form of salad, with plenty of vinegar, pepper, oil, and onions. On the fifth day he takes alternately, every two hours, one third of a herring, and a heaped-up tea-spoonful of pulv. rad. filicis maris, and with this two to three cups of coffee. At night a milk clyster and a dessert-spoonful of castor-oil. On the sixth morning, fasting, two tea-spoonfuls of fern-powder; an hour afterward, two table-spoonfuls of castor-oil, and the same quantity every two hours until the worm is expelled. During this he drinks tea; and, lastly, for the subsequent treatment, iron is used."

173. (k) *Ullersperger's Method*.—Without any previous treatment, he gives  $\mathfrak{z}$ ij.— $\mathfrak{z}$ iv. of the bark of the roots freshly peeled, treated with alcohol the day before, and lets the patient lie in bed. When no vomiting takes place within two hours, an aperient of 6 gr. calomel and  $\mathfrak{z}$ j. of sapo jalap. in pills is given. This method is said to be rapid and efficacious.

174. (l) *J. P. Frank's method* is to commence either with the exhibition of tin, as above, and to follow with the *male fern*, or to begin at once with this latter, giving about three drachms in a draught of cold water, and to give frequently cold diluents, allowing the most rigorous abstinence. A dose of castor-oil may be taken the following day, and repeated every two hours until copious evacuations are procured.

175. (m) *Mayer's and Karsten's Methods*.—On the day when fragments pass off spontaneously, the patient takes a herring salad at night. At six o'clock next morning,  $\mathfrak{z}$ ij. of fern-powder in  $\mathfrak{z}$ vj. of aq. flor. tilis is taken in tea-spoonfuls without stopping, and immediately after this a table-spoonful of castor-oil, and then a cup of thin broth. The oil is then continued every half hour until  $\mathfrak{z}$ ij. are taken. For any sensation of fulness and nausea, hot black coffee is given. About twelve o'clock the greater part of the

worm is expelled, and the head passes at one or two o'clock. Bitters are prescribed subsequently. KARSTEN'S method consists of a mild aperient and scanty diet the day before; and early in the morning,  $\text{zij}$ . of fern-root in teaspoonfuls. If sickness be felt, thin broth is given. Between eleven and one o'clock the worm is expelled without any farther treatment. Several other methods of employing the male fern root have been enumerated by KÜCHENMEISTER, generally premising various means, the modus operandi and utility of which are not very apparent. I shall next notice two other preparations of this root—the *extract* and the *æthereal oil*, which have been used with great benefit. The *compound decoction of male fern*, for which I have given a *Formula* in the APPENDIX, will be found one of the most efficacious modes of prescribing this remedy. (See *Form.* 62.)

176. (n) The *extractum filicis maris* has been prescribed by several physicians. PESCHIER administers it as follows:

No. 384. R Extr. Filicis Maris Æther.,  $\text{Oj}$ .— $\text{3ss}$ .; Pulv. Rad. Fil. Mar., q. s., ut fiant Pillule xx.

To be taken in two portions half an hour before bed-time, after fasting from five o'clock in the evening; next morning an aperient. Several physicians have adopted this preparation and its mode of exhibition with success. KIESER and HILLER gave the extract, for several days together, to the total amount of  $\text{zij}$ . with good results. After several days of spare diet, MÖSING gave fifteen of PESCHIER'S pills to the fasting patient at nine o'clock, and again at half past nine. His prescription is as follows:

No. 385. R Extr. Filicis Maris Æther.,  $\text{3jss}$ .; Pulv. Rad. Fil. Mar., q. s., ut fiant Pillule xxx.

After the last dose, he gave  $\text{zij}$ . infusi sennæ compos. at once. FUNK administered the extract night and morning with sirup and gum, and afterward gave castor-oil every hour until it operated freely. NOSS prescribed an aperient on the preceding day, and the extract to the fasting patient with sirup— $\text{Oss}$ .— $\text{3ss}$ . of the extract twice with an interval of an hour; then castor-oil every hour. ALBERS, after a restricted diet for one to three days, and on the day before the exhibition of the extract, prescribed a purgative of Glauber's salts; and on the following morning,  $\text{3ss}$ . of extract of male fern while fasting, and the same quantity an hour afterward; one to two hours afterward, castor-oil. RAYER gave seventy-two drops of PESCHIER'S thin extract of fern made into pills with the powder of the root, of which eight are to be taken at night, and eight in the morning; two hours afterward, castor-oil. MAGENDIE prepared a *tincture* from the buds of the fern, and made it into pills with the powder of the bark of the root, each containing a drop of the tincture. From eight to twenty were said to be sufficient for expulsion of the worm. The circumstance of no farther accounts of the employment of this tincture having appeared is not in favour of its efficacy.

177. (o) The *æthereal oil of male fern* has been much employed and praised by Dr. JENNER. He caused the patient to be kept without food for sixteen or eighteen hours before he gave the oil; and he farther recommends the following mode of administering it: "For an adult, two pills may be taken at bed-time, containing three grains of calomel, and eight of compound colocynth pill; the following morning, a dose of castor-oil. A lit-

tle broth only should be given till the bowels have been thoroughly cleared out. As soon as that object is effected, one drachm and a half of oil of male fern is to be given on an ounce of some aromatic water; and the dose of oil of male fern is to be repeated in six hours, if the first dose has not proved effectual before the expiration of that time. For a child, calomel and jalap may be substituted for the colocynth and calomel. The dose of the oil of male fern must be as large for the child as for the adult; seeing that its action is on the parasite, and not on the patient, I have never seen any unpleasant results follow its employment in the child." I have, in several cases, given the male fern successfully, when connected, many years ago, with public medical institutions; and since the publication of Dr. JENNER'S interesting paper on the use of the *æthereal oil of male fern*, I have prescribed it in two cases—in one with complete success, but in the other it failed. In this latter, the oil of turpentine and the kousoo had been prescribed separately and after considerable intervals, and both had failed, portions of the worm only having come away. An opportunity, however, was not afforded me of persevering in the treatment beyond the exhibition of two doses of two drachms each. The oil was procured from an undoubted quarter. I give, in the subjoined note, Dr. JENNER'S account of his experience with this oil.\* In a case re-

\* "The anthelmintics chiefly employed in cases of tape-worm in this country are turpentine, kousoo, pomegranate, and male fern. The objection to turpentine is its horribly nauseous flavour, and its very unpleasant effects on the head, and occasionally on the kidneys. It is a remedy which should be used only as a last resource. Kousoo is expensive and bulky. Pomegranate is bulky and nauseous, and, as ordinarily obtained in this country, not very certain in its action. Male fern has the advantages of being inexpensive, only moderately disagreeable in flavour, so that children take it readily, of small bulk, perfectly innocuous to the patient, and more certain than the other agents in its action on the parasite. It is one of the oldest of the remedies for tape-worm, and one of the very best. The preparation I have used is the *æthereal oil*. An aperient was given in the morning, the patient was kept without food for sixteen or eighteen hours, and then one or two drachms of the oil of male fern were administered on a little cinnamon water.

"I have notes of twenty-four cases to which the oil of male fern was given. Sixteen of these cases were cured by a single dose. In three of these sixteen cases the head was found; three of the remaining thirteen were ascertained to be well two years after the administration of the oil, one a year after, one seven months, two six months, three four months, one three months; and before the other two ceased to be under observation, a second dose was given by way of precaution, as it was to all the patients when the head was not found, without any tenia coming away with the stool.

"Three required two doses of the drug; in one of these three, some yards of tenia were expelled by the first dose; for two months after this no joints were found in the stools, then a few appeared, and a second dose was given, and was followed by the expulsion of nine yards of tenia; the patient continued well two years after this. In the second case, three yards were expelled by the first dose; and a month after, five feet by a second dose; at the expiration of four months and a half, the patient continued well; in the third case, five and a half yards of tenia were expelled by the first dose, and seven yards by the second, given two months after the first.

"Three doses were required in two cases. The first dose of the oil, however, given to one of these cases, was not of good quality. In one of the two three days elapsed between the first and second dose, and four hours between the second and third. In the other two days elapsed between the first and second dose, and one between the second and third. In both cases the head was obtained.

"In one case, viz., that of a child five years and six months old, between the 15th of July and the 4th of August inclusive, five doses of castor-oil, and as many of oil of male fern, were administered without a decided effect; a few joints of tenia only being expelled. On the 17th of August, twenty grains of the extract of male fern,

corded in the same journal (August 30, 1856, p. 733) by Mr. SYMPSON, two drachms of the æthereal oil of male fern, given without preparation, brought away the *Bothriocephalus* in three hours after their exhibition, the worm being voided in two portions with its head connected with the part last voided.

178. *c. METHODS WITH POMEGRANATE BARK.*—DIOSCORIDES, CELSUS, and PLINY mention the *radix punice granati* as a vermifuge; and in the East its reputation as an anthelmintic remedy has been great from time immemorial. It was introduced into Europe early in this century by BUCHANAN, BRETON, FLEMING, and others. SEEDER states that of 419 cases treated with it up to 1852, 371 are reported as complete cures, 24 as doubtful, and 24 as unsuccessful. KÜCHENMEISTER adds that he could considerably increase the number of successful cases, partly by his own observations, and partly by those made by others, according to his method—this appearing to be his favourite remedy. The following inferences are stated by him as to the preparation of the bark: 1st. All experiments to ascertain the active principle of the bark of the *radix punice granati* have failed. 2d. This bark is often adulterated, or contains much impurity. 3d. The bark of the root is more active than the bark of the trunk;  $\mathfrak{z}\text{ij}$ . of the former =  $\mathfrak{z}\text{iv}$ . of the latter. The bark of the branches has no action. 4th. The fresh bark acts more gently than the dried bark, but more of it is required;  $\mathfrak{z}\text{ij}$ . =  $\mathfrak{z}\text{ij}$  of dried bark. 5th. According to several authorities, the East Indian bark—which is thicker—should be preferred to the European. 6th. “After maceration for at least twelve to twenty-four hours, the bark is well boiled; and, according to CENEDELLA, it is better made in earthen than in metallic vessels; it is filtered while hot, as, on cooling, active substances appear to be thrown down again. The decoction was formerly most generally used, but I prefer the extract. The best method of preparing this is as follows:

No. 356. R. Corticis leviter contusi Rad. Punice Granati,  $\mathfrak{z}\text{iv}$ .; maceantur per horas xxiv. cum aquæ destill.  $\mathfrak{v}\text{ij}$ .;

obtained from Duncan and Floekhart, of Edinburgh, were given without effect. On August 23d, one pint of infusion of pumpkin-seeds; on September 1st, decoction of pomegranate; and on September 5th, infusion of kousoo; all produced copious evacuations, but no tape-worm. The child now left the hospital. In November he was readmitted, and, during my absence, was treated with success, by my friend Dr. BALLARD, with the oil of male fern. This time the child was kept for forty-eight hours with little, if any, food, before the oil was given. The child was free from tape-worm some months after he left the hospital.

“One man took the oil two or three times without any good effect; but then large quantities of solid feces were discharged from its action; and before it could be administered in a more effectual manner, the patient escaped observation.

“Among those cured by a single dose, and well two years afterward, was one man who had taken kousoo three times, and oil of turpentine twice. Several of the others had taken turpentine and other remedies with permanent good effect. In three cases (children), the patients rejected the oil by vomiting; with one exception, all admitted that it was much less nauseous than castor-oil. In no case did it cause griping or other unpleasant symptoms. The shortest time after taking the oil in which the worm was expelled was half an hour; the longest twelve hours; the ordinary time four hours. A large quantity of tenacious yellow mucus was usually expelled either with or before the worm, and often, also, when no worm was present, as when the oil was given to ascertain that no worm remained, the head not having been found.

“In no case was the worm alive when expelled, and in no case was it expelled entire.”—(*Association Med. and Journ.*, Aug. 23, 1856, p. 718.)

posthæc coque in leni calore per horas xij., ad remanentiam,  $\mathfrak{v}\text{ij}$ . et cola.

To be taken in three to four doses at intervals of from half an hour to an hour.” 7th. According to German physicians, the fresh bark, or the extract prepared in the East Indies from the fresh bark, is to be preferred. Even the fresh bark cultivated in Germany and in green-houses is more efficacious than the dried bark. WAITZ’s extract, prepared from the fresh bark in the East Indies, is very active, the dose of it being  $\mathfrak{z}\text{ij}$ .— $\mathfrak{z}\text{ij}$ . 8th. “The most efficacious form, under all circumstances, is the solution of the extract in a certain quantity of water. The extract itself, made into an electuary with honey, or administered in pills, is to be recommended where there is great tendency to vomit, but, on the whole, its aqueous solution is the best. 9th. An alcoholic extract is also recommended by DESLANDES, and recently by MARTINS, and an æthereal extract has been prepared by WAITZ in Java. Of the latter  $\mathfrak{z}\text{ij}$ — $\mathfrak{z}\text{iv}$ . are administered in  $\mathfrak{z}\text{v}$  of fennel-water with syru<sup>i</sup> corticis aurant  $\mathfrak{z}\text{ij}$ ., in three doses, at intervals of half an hour.” 10th. Although boiling water is, to a certain extent, sufficient for the preparation of the active substance of the bark, yet the addition of caustic potash or soda, or of a little white wine to the water employed in the maceration, and afterward in the decoction, of the bark, greatly increases the efficacy of the extract. 11th. Bark which has been long kept is to be rejected as inefficacious. 12th. KÜCHENMEISTER has recourse to another method of preparing the decoction and extract beside that advised above (6th.) It is as follows:

No. 357. R. Cort. Rad. Punice Granati,  $\mathfrak{z}\text{v}\text{ij}$ .; Pulv. Khamni Cathart.,  $\mathfrak{z}\text{ij}$ .; Aquæ Destillat.,  $\mathfrak{v}\text{ij}$ .; Liq. Kali Caustici Concent.,  $\mathfrak{v}\text{ss}$ . Macera per horas 12—14; coque in leni calore in balneo vapor. per horas 24 ad remanentiam extracti.

The woody parts are to be removed by washing and pressing some time before the conclusion of the evaporation, the washing water being evaporated with the rest. A quantity of this extract, corresponding with the dose of the pomegranate bark prescribed, is to be dissolved in  $\mathfrak{z}\text{v}\text{ij}$ .— $\mathfrak{v}\text{ij}$  of hot water; and, before administration,  $\mathfrak{z}\text{ij}$ .— $\mathfrak{z}\text{ss}$ . extracti filicis maris æther. may be added, when it is desired to combine the two extracts. (See § 176.)

179. *d. METHODS OF PRESCRIBING POMEGRANATE BARK.*—(a) *Recent Bark.*—BUCHANAN prescribes  $\mathfrak{z}\text{v}\text{ij}$ . of fresh bark of the root to be boiled with three pints of water until two pints remain, and drunk in cupfuls at short intervals, until the worm is expelled. KÜCHENMEISTER says that by this violent vomiting, colic, and purging are produced. BRETON recommends  $\mathfrak{z}\text{ij}$ . of the fresh bark to be boiled down from  $\mathfrak{z}\text{v}\text{v}\text{ij}$ . to  $\mathfrak{z}\text{iv}$ ., or, according to GOMEZ, from  $\mathfrak{v}\text{ss}$ . of water to  $\mathfrak{v}\text{ss}$ ., and this decoction to be taken by cupfuls. MÉRAT advises  $\mathfrak{z}\text{ij}$ . of fresh bark to be infused at night in  $\mathfrak{v}\text{ss}$ . of water, and left to macerate through the night, and to be boiled down to  $\mathfrak{v}\text{ss}$  in the morning. After being filtered and well pressed, this decoction is to be taken in three equal parts within two hours. If vomiting occur after the first dose, this should not prevent the following doses from being given; but if the patient vomit these the treatment must be desisted from. According to SCHMIDTMEYER, after one day’s fasting, and the administration at night of  $\mathfrak{z}\text{ij}$ . of castor-oil,  $\mathfrak{z}\text{ij}$ . of fresh bark are macerated for twelve hours in  $\mathfrak{z}\text{v}\text{ij}$ . of water, and concentrated to  $\mathfrak{z}\text{v}\text{ij}$ .; this is taken in three doses within an

hour. KÜCHENMEISTER remarks that “in all these methods evacuations take place without purgatives, as the fresh bark usually acts as an aperient itself; and in this lies the great advantage of the fresh bark, and a principal cause of the great uncertainty of most of the previous methods, in which the dried bark was employed. To produce the aperient action with certainty, the dried bark needs the addition of purgatives. According to my experience, the neutral salts and the true drastics, such as jalap, are greatly to be preferred to the oils.” The decoction of fresh pomegranate bark may also be prescribed as stated in the APPENDIX. (See *Form.* 69.)

180. This writer prefers the extract. *radicis punice granati*, prepared according to the prescription given above (§ 178, No. 387), to all other remedies for tape-worm with which he is acquainted; for, in almost every case of expulsion by this medicine, the worm was passed in one piece with the head, or unbroken and in a single coil—sufficient reason, in his opinion, for endeavouring to make the administration of this remedy more agreeable, and its results still more certain.

181. (b) *Combinations of Pomegranate Bark and Male Fern.*—This was attempted by VON KLEIN, and afterward by KÜCHENMEISTER. The latter prescribed it as follows:

No. 388. R Extracti Radicis Punice Granati Aquosi quantum est ex Rad., ʒiv.—ʒvj., solve in Aq. Destill. Fervidæ, ʒvj.—viij. Adde Extr. Filicis Maris Æther., ʒj.—ʒss.; Extr. Tanacet. Vulgaris, ʒij.; Cambogiæ, gr. iv.—vj. ad x. Misco.

A cupful to be taken in the morning, fasting; a similar dose in three quarters of an hour. The third is kept in reserve. If the worm be not expelled in an hour and a half after the second dose, the last portion is also to be taken. If vomiting occur, a table-spoonful of the medicine is given every ten minutes; and, to alleviate the tendency to vomit, the patient is recommended to gargle, after every dose, with fresh milk, without swallowing any of it. Small pieces of candied citron or lemon-peel are allowed between the doses. If no evacuation have occurred three hours after the first dose, and the worm have not been expelled, an aperient is administered. “With *tania solium*, castor-oil is usually sufficient; one to two table-spoonfuls every half hour or hour; or,

No. 389. R Cambogiæ, gr. vj.—viij.; Pulv. Rad. Jalapæ, gr. x.—xv.

To be repeated in two hours, if required.” With *T. mediocanellata*, this writer has found the best results with the following aperient:

No. 390. R Calomelanos, gr. iv.—vj.; Pulv. Jalapæ, gr. x.—xv.

To be taken at once. After the expulsion of the worm, he advises no treatment, excepting tonics in cases of great weakness.

182. (c) *The preliminary treatment, advised by KÜCHENMEISTER*, is as follows: At the seasons of fresh strawberries and grapes, he gives half a pint of these fruits every morning, fasting, for six to eight days; and on the evening before the expulsion, a herring salad with plenty of vinegar, onions, raw and boiled ham, and plenty of oil; and to very costive persons, ʒj. of castor-oil; after which the patient may drink a large glass of light Rhenish wine, or a glass of bitter beer. If the fresh fruits are not to be had, the salad alone will suffice. In very obstinate cases

of *Tania mediocanellata*, he allows the patient to take as much confection of senna with extr. tanaeti vulg. (ʒij. to the ounce of the confection) as will produce two soft motions daily; he then takes the mixture, and not before. Fasting the night before is not advised, as the medicine does not agree well with an empty stomach.

183. e. METHODS WITH OIL OF TURPENTINE.—I have prescribed this medicine both as a preliminary means variously combined, and as a direct remedy, or after little or no previous treatment. As a preliminary medicine, I have most frequently given it in the following form:

No. 391. R Olei Terebinthinæ, ʒij.—ʒiv.; Ætheris Sulphurici (vel Spirit. Ætheris Sulph. Comp.), ʒiv.—ʒj.; Tinct. Camphoræ Comp. (vel Tinct. Benzoniæ Comp.), ʒss.; Olei Cajuputi, ʒxij.—xx. Terc. cum Pulv. Traga-canth. Comp., ʒij.; Pulv. Glycyrrh., ʒij., et adde Syrupi Rosæ et Syrupi Tolutani, aa, ʒss., Aquæ Destill., ad ʒviij. Fiat mist. cujus capiat cochl., j. vel ij. larga, 4tis vel 6tis horis, prius agitata phialâ.

Cold water, or linseed tea, barley water, &c., may be taken frequently during the continuance of this medicine; and in some cases, as soon as any indication of disorder of the urinary functions occur, a full dose of either castor-oil, or of calomel with camboe or jalap, so as to freely evacuate the bowels, should be given. Frequently a considerable portion of the worm is expelled by these means; but nevertheless the male fern, or its æthereal oil, or the pomegranate bark, should be taken, as prescribed above (§ 164–181), a few hours after the exhibition of the purgative; or in other cases a few hours before, especially if the bowels have not been long confined.

184. KÜCHENMEISTER states that “the dose of this remedy is ʒij. at once, in the morning, fasting; and if no stools result, another ʒj.—ʒij. afterward (FENWICK and COPLAND); or ʒj. olei terebinthinæ, made into an electuary with honey, &c., in two doses at night before going to bed (THOMPSON); or ʒij.—ijss. (SCHMIDTMANN); or with the olei filicis maris (MAYOR). Or the patient for three days is allowed to eat only water-gruel with small portions of white bread, three times a day; and on the next day, when fasting, to take the following:

No. 392. R Olei Terebinthinæ, ʒj.; cum Vit. Ovorum, ij.; Sacchari Albi Subacti, ʒss. M;

and if the worm is not expelled on this day, the dose is repeated on the following day (MERCK). Some also give ʒij.—ijss., one half in the morning, and the other at night.” This is one of the most effective agents against tape-worms, as LANGE, KÜCHENMEISTER, and others admit. The latter of these writers states that tape-worms laid in turpentine mixed with white of egg, died within one hour and three quarters; and that the touch-stone of a remedy for tape-worms is not whether it expels *Bothriocephalus latus* or *Tania solium*, but whether it is also capable of expelling the *T. mediocanellata*. That the oil of turpentine is efficacious in the latter case, he can prove; for the finest specimen of this last-named worm was expelled by it. In general it acts with tolerable rapidity, and entirely. This latter circumstance he regards as a requisite of a good vermifuge in cases of tape-worm, especially as the doctor and the patient are anxious to ascertain the expulsion of the head of the parasite.

185. The principal objections to this substance are its nauseous taste, the inclinations to vomit, the unpleasant eructations, griping pains, and disorders of the urinary excretion, it often occa-

sions. It more frequently produces these unpleasant effects when taken in the form of an electuary. When prescribed in the form of mixture, as above (§ 183), or suspended by white of egg, or taken either pure in a full dose (ʒj.—ij.), or with the addition of castor-oil, on the surface of coffee, or milk, or on any aromatic water, at bedtime, or early in the morning, it is generally the most efficacious, and least likely to produce any of the above unpleasant symptoms. It is often taken with less discomfort on the surface of Hollands or common unsweetened gin. When castor-oil is not given with it, and when it does not act on the bowels in a few hours, either a full dose of castor-oil, or of some one of the purgatives already mentioned, should be taken without delay.

186. *f. METHODS WITH KOUSSO.*—*Kosso*—*flores kouso*—the dried and powdered flowers of the *Brueya anthelmintica*, has lately been much in vogue against tape-worm. It has been supposed by several physicians to have been adulterated. KÜCHENMEISTER supposes that it is not so much adulterated as mixed with other Abyssinian medicines against tænia, as with the powder of the root of *Verbascum ternstro*, and with the powdered leaves of *Jasminum floribundum*. The dose of the powder of kouso is ʒvj.—ʒj. I have prescribed this remedy in four cases. In the first, successfully in the case of a medical man in Hertfordshire, the entire worm with the head having been brought away after turpentine and some other anthelmintics were said to have failed; and in two cases with only a partial benefit; and in one case without any effect. The writer just mentioned states that he has always been more or less unlucky with this remedy, which, in the ordinary mode of administration, shares all the defects of the other remedies for tape-worms, and easily produces sickness and violent pains in the intestines; and that the worm has generally been expelled by it in numerous fragments, and at most the worm up to the neck; but that he never found the head, excepting once, after a second dose of the kouso, which caused violent pain in the abdomen. Several attempts have been made in Germany to isolate the active constituents of this substance, and to prepare infusions, decoctions, and infuso-decoctions of it, with and without the flowers being retained in them; but although the effect appeared to equal or to approach that of the powder of kouso itself, yet little was gained, excepting when the quantity (ʒvj.—ʒj.) of kouso usually employed was macerated in cold water for twenty-four hours, and then boiled for half an hour, and the whole taken—without straining—with the flowers in it, in two portions; ʒj. to ʒij. of castor-oil having been given two hours after the second portion. This infuso-decoction was said to have been well borne, and to have acted with certainty.

[To avoid the nauseating effects of kouso flowers, however different the mode of administration, the resin of the flowers, extracted in the same manner as the resin of jalap, has been recently recommended. Two scruples to one drachm of the resin are dissolved in about three drachms of alcohol. This solution is then poured on a piece of sugar weighing about half an ounce. After the sugar has dried by evaporation of the alcohol, it is powdered, three drachms of powdered sugar being added. The whole is then divided into five doses, four of which are given at six, seven, eight,

or nine o'clock in the evening; the remaining at six o'clock in the morning; an hour later, six to nine drachms of Glauber's salts are given, dissolved in water.]

187. *g. NOTICES OF SEVERAL OTHER MEDICINES AND METHODS AGAINST TAPE-WORMS.*—(a) The *Spigelia anthelmintica* has been employed, according to NOVERRE, in the West Indies; but its effects are unpleasant, and it not easily admits of use in Europe.—(b) *Sabadilla* has been given in a dose of half a drachm of the powder in the morning, the patient having been purged on the previous day with rhubarb and Glauber's salts. The sabadilla powder is given with the same quantity of fennel sugar, and the patient afterward drinks one to two cups of chamomile or elder-flower tea. If vomiting be produced, worms in the stomach are thrown up. On the second day the same dose of sabadilla is taken; and if no more of the worm appears, half the quantity of this medicine is taken morning and evening of the third and fourth days. On the fifth morning, while fasting, a purgative is administered, and the living or dead worm is brought away. For children from two to four years, two grains of sabadilla powder is a sufficient dose. This medicine is of service against *ascarides*.—(c) The *schebdi*—the *Phytolacca dodecandra* or *Abyssinica*. The fruit of this plant has been tried in Europe, and fragments of the worm have been brought away; but sufficient trials have not been made of its efficacy.—(d) The *fructus saoria*, the fruit of *Masa picta*, HOCHSTETTER, has been given in doses of ʒj.—ʒjss. with uncertain results. This remedy is easily taken. Its taste is less repulsive than that of other remedies. Nausea, vomiting, and slight pain in the abdomen are often experienced from it. In two cases the worms were expelled by it up to the head, but always in fragments. This remedy appears to be deserving recommendation for *ascarides* and *oxyurides*.—(e) The *Mucuna*—*cortex mucuna*—from *Mucuna anthelmintica*. The dose of the powder is ʒvj., and is usually, in the East, given with honey in a stiff paste. Single fragments of the worm were brought away by it, but the medicine was probably injured by keeping.

[The *petroleum* has been found very successful in the treatment of tape-worm. The mode of administering is to combine half an ounce of the petroleum with six drachms of the tincture of asafoetida, and give forty drops three times a day.

The seeds of the pumpkin (*Peponis semen*) have recently obtained considerable reputation for the cure of tape-worm. They have the very remarkable property of being bland and almost tasteless, while at the same time they yield to few, if any, anthelmintics in point of efficacy. Two ounces, or even more, as they are perfectly harmless, may be given for a dose. They should be taken upon an empty stomach in the morning, before breakfast; first depriving them of their outer covering and rubbing them into an electuary or paste, with sugar and a little water; or a larger quantity of water may be added, forming an agreeable emulsion. The whole should be taken in successive draughts, and in two hours after followed by a full dose of castor-oil.]

188. *h. DRASTIC PURGATIVES WITH AND WITHOUT CALOMEL.*—BREMSER's and SCHMIDT's methods of employing these medicines are too severe, and are often productive of inflammation of the digestive mucous surface, which may not be al-

laid for some weeks. I will not, therefore, mention them. According to ETTMÜLLER's plan, the patient takes, at seven o'clock in the evening, calomel., gr. xij., lapid. cancor., ʒj.; and about nine o'clock, olei amygdal. dulc., ʒjss.; which usually operate twice in the night. At seven and nine o'clock next morning he takes cambogiæ, gr. xij., rad. valerianæ, and sem. cinæ, āā, gr. iv., when the worm is afterward expelled. I much doubt this result. It is quite unnecessary to state the various modes in which the changes are rung upon the purgatives believed to be most appropriate in cases of tape-worm, by writers of no mean reputation, and the several ways these medicines may be combined and successively administered. Calomel, camboge, jalap, castor-oil, the sulphates of potash, soda, magnesia, &c., variously conjoined or administered in succession, with or without valerian, oleum tanacetii, &c., are the chief medicines advised. But, in order to be efficient, their doses and the repetitions of them are such as to risk the supervention of inflammation; and in a large proportion of cases they fail altogether.

189. i. INFERENCES.—(a) Simple methods of treatment with the *flux mas* and its *æthereal oil* and *extract* (§ 176, 177), are sufficient to remove the *Bothriocephali*.—(b) For the expulsion of *Tænia solium*, the combination of the aqueous extract of the bark of the pomegranate root, with the addition of the *æthereal extract* of male fern, is considered by KÜCHENMEISTER as the most efficacious, camboge, gr. iv.—viij., being preferable to the saline addition mentioned above.—(c) The *Tænia medocancllata* is generally expelled by the same combination, especially when a powder with calomel and jalap, or camboge, is given afterward.—(d) In very obstinate cases, the methods with tin, or those with turpentine, or with these latter following the former, may be employed with care and circumspection.—(e) The kousso does not promise any advantage over the above remedies, if, indeed, it be equal to any of them.—(f) When the worms depend from the anus, the German physicians advise a cup of strong black coffee with plenty of sugar to be given immediately. A dose of calomel and jalap, or this followed by castor-oil, appears to be more efficient.

190. k. TREATMENT WITH KAMALA (*the red powder obtained from the capsules of Rottlera tinctoria*, Roxburgh).—This substance, long known in India as a valuable dye for silk, has been much employed against tape-worm, which is very prevalent in the Punjab and Northwestern Provinces of India, and has recently been prescribed with success in this country by Dr. LEARED and others. This peculiar red powder may be prescribed in doses of half a drachm to three drachms suspended in water. "A single dose is often found sufficient, and in general it is not necessary to give any other medicine before or after. In some cases, however, where a small dose of kamala has been administered, castor-oil has been afterward given with good effect. Dr. GORDON has prescribed kamala in the dose of one drachm, repeated at intervals of three hours. Kamala may be given also in the form of tincture, the formula for which, recommended by Dr. ANDERSON, is as follows :

No. 393. R Kamalæ, ʒvj.; Spiritus rectificati, ʒxvj. Marcera per biduum et cola.

An *æthereal tincture* may be prepared of the

same strength; but it is said to offer no particular advantage over the alcoholic. The dose of *tinctura kamalæ* is from ʒj to ʒiv., diluted with some aromatic water." (Dr. HANBURY, in *Pharmaceutic Journ.*, Feb., 1858, p. 405.)

191. Drs. C. MACKINNON, ANDERSON, CORBYN, and GORDON have praised the anthelmintic powers of this medicine. Dr. MACKINNON states that the results have been so satisfactory, that he has continued to employ this whenever a case of *tænia* presented itself, and that he has given it in sixteen cases without a single failure. In none of his cases, excepting one, did he ever exceed, for a single dose, three drachms. This dose usually purges from five to seven times; and the worm is usually expelled, dead, in the fourth or fifth stool. In about half the cases some degree of nausea and slight griping were experienced; in the remaining half no inconvenience whatever was felt. Dr. MACKINNON states the following as the results of his experience of this medicine: "1st. That kamala is a safe and efficient remedy for tape-worm, and more certain than either turpentine or kousso. 2d. That, to a strong European, three drachms may be safely given as a dose. 3d. That to a person of feeble habit, or to a female, one drachm and a half, followed, if necessary, by half an ounce of castor-oil, is a sufficient dose." Since the above was published, Dr. MACKINNON has administered this medicine to nearly fifty patients, and in two instances only was no worm expelled. (*Medical Times and Gazette*, Dec. 19, 1857, p. 628; and *Indian Annals of Med. Science*, vol. iii., p. 86.)

192. Dr. ANDERSON states that, "after three drachms of the powder (of kamala) have been administered, the worm is usually expelled in the third or fourth stool. It is generally passed entire, and almost always dead; and in all the cases I have examined (about fifteen) I was able to detect the head. In only two cases do I know of the worm being passed alive. The advantage of the tincture over the powder consists in its action being more certain and milder, and in its being rarely accompanied by nausea and griping. In two or three cases, only two or three stools followed the dose usually given, and the worm was expelled in the second stool; in one patient, only one stool was caused by the medicine, and in it the worm came away dead." (*Ind. Ann. of Med. Sc.*, vol. iii., p. 82.) Dr. ANDERSON alludes to ninety-five cases of tape-worm in which kamala was prescribed, and of this number (eighty-six were European soldiers) he was aware of only two in which no worm was expelled. Dr. C. A. GORDON remarks that "with this medicine there is no unpleasant effect. It is not even necessary to take a dose of purging medicine as a preparative; and, beyond a trifling amount of nausea and griping in some instances, no unpleasant effects are experienced; while by far the greater number of persons to whom it is administered suffer no inconvenience whatever beyond what they would from a dose of ordinary purging medicine." (*Med. Times and Gaz.*, May, 1857, p. 429.)

193. Dr. ANDERSON and Dr. GORDON agree in stating that the frequency of *tænia* in the North-west and Upper Provinces of India arises from the free use of animal food of a very unwholesome character by the European soldiers; while among the Hindoo natives, whose food is entirely vegetable, this parasite is unknown. Foul-feed-

ing and half-starved pigs, cattle and sheep, as well as ducks, turkeys, fowls, pigeons, equally foul-fed and diseased, are often made articles of diet by the European soldiers, and are justly viewed, by the physicians mentioned above, as the causes of the prevalence of tape-worm in this class.

194. iii. TREATMENT OF THE OTHER WORMS.—*A. Echinococi, cysticerci, and accephalocysts* rarely admit of treatment, and only of surgical treatment. This subject is sufficiently noticed in the article HYDATIDS.

195. *B. The comparative rarity of the Distoma hepaticum* (§ 98–100), and the difficulty of its diagnosis, render the prophylaxis and treatment of this worm, in some respects, matters of subordinate importance. The prevention is either difficult or impossible, owing chiefly to our imperfect knowledge of its developmental history. As far as this history may be inferred from the subjoined remarks of KÜCHENMEISTER, the prophylaxis must be founded on it, and be viewed as conformable with what has been stated above.\* (§ 157–160). The direct treatment of *Distoma hepaticum* can rarely be ventured upon with success, owing, first, to the almost impossibility of its diagnosis, unless its presence be inferred from the passage upward or downward of some individuals of this species; and next, from the serious nature of the lesions produced by it. Even granting, then, the detection of the malady, medicines can be exhibited only with great uncertainty as to their beneficial effects. As, in many of these cases, the biliary functions are more or less interrupted, and organic vital force impaired, it becomes necessary to attempt the restoration of the former, and the development of the latter, by suitable means. To remove biliary obstruction, calomel and other mercurial preparations combined, according to the peculiarities of the case; the nitro-muriatic acids internally and externally; the preparations of taraxacum, and the mineral waters of Carlsbad, Marienbad, Kissingen, and similar springs. DURAND's medicine against gall-stones and obstruction of the gall-ducts has also been recommended. This medicine consists of equal quantities of oil of turpentine and sulphuric ether. It may be given in moderate and frequent doses; or the oil may be conjoined with alcohol, or with nitric ether, or with the sweet spirits of nitre. These appear to be appropriate for this

parasite, as the efficacy of the turpentine against other worms, and the rapidity of the absorption of it into the circulation, are indications in favour of the use of it in cases where the existence of this animal is inferred. KÜCHENMEISTER states that the principal ingredient of the remedy of DURAND has been successfully administered for *distoma* of some of the lower animals; and that, upon his recommendation, turpentine was administered to several sheep, and followed by a purgative; but the results were not fully ascertained when he wrote. The propriety of enabling the constitution to throw off the parasitic animal by the exhibition of tonics conjoined with alteratives and deobstruents, such as the bichloride of mercury with preparations of cinchona; the extract of taraxacum with the solution of potash, and with tonic and bitter infusions or decoctions; and the nitro-muriatic acids with these latter and with taraxacum, cannot be reasonably doubted.

196. *C. The Distoma hematobium*, so remarkably prevalent in Egypt (§ 103–109), cannot be encountered with any means of prevention or of cure, upon which any reliance may be placed. GRIESINGER, who has furnished the chief amount of information respecting this parasite, considers that—1st, the waters of the Nile used without filtration; 2d, the bread, grain, and dates employed for food; and, 3d, the use of half-putrid fish, being the chief causes of its existence—the prevention of it must be based on the avoidance of these causes, and of the circumstances connected with them, which admit of avoidance. As regards the cure, calomel and turpentine are chiefly recommended by GRIESINGER, the latter being readily absorbed into the circulation, as first shown by me in a memoir on this remedy, published in the *London Medical and Physical Journal* for 1821. He also advises the use of onions, garlic, &c. The tinctura ferri muriatis, and other preparations of iron, of camphor, asa-fetida, &c., variously combined, and long persisted in, may also prove of benefit, especially as anæmia and chlorosis form a marked characteristic of these cases.

197. *D. The Oxyuris vermicularis* (§ 123–126) is always treated with difficulty, and, according to my experience, with greater difficulty in old than in young subjects. KÜCHENMEISTER states that internal remedies in general are but little to be recommended. I am of a very different opinion, based upon very considerable experience. This writer advises the long-continued use of a tea made from the *flores verbasci*. The flowers are left in the infusion, and used with it. The fine hairs appear to irritate and disturb the worms mechanically. The remedies already noticed for the cure of tape-worm, especially turpentine, the pomegranate root, the filix mas, &c., often bring away the thread-worms, but they are soon regenerated. The permanent removal of them cannot be effected by these or by similar means. Medicines calculated to act upon the lower bowels, and to restore the tone of the digestive mucous surface, and to correct the state of the intestinal secretions and excretions, are especially required against these worms. Dr. PÖCKELS recommends the powder of filix mas and jalap in some suitable vehicle; KÜCHENMEISTER, the preparations of the semen cinæ—the santonium, or semen contra vermes—internally for two days, and afterward strong purgatives, followed by clysters; DUJARDIN advises enemata with valerian, or garlic, or

\* Although it is still unknown to us how the embryo becomes metamorphosed, and into what *cercaria-sacs* or *redie* it is converted, and where these *cercaria-sacs* or *redie* live; although we do not know whether the brood of *D. hepaticum* is tailed or tailless, and where it encysts itself, whether free in the water in the manner of *Monostomum*, in aquatic mollusca or insects, or in higher animals which occasionally visit stagnant waters, yet there is much probability that the herbivorous or omnivorous domestic mammalia infect themselves with free encysted young *Distoma*, either by devouring snails which adhere to the grass of the meadows, especially in moist pastures, or by drinking from impure, stagnant waters (marsh or pond water). Exactly the same thing would then take place in man, by means of snails adhering to salad, fallen fruits, radishes, turnips, and other roots. Nay, such small snails might even be introduced with dry fodder into the stomachs of our domestic animals during the winter, by their eating the small species, passing their winter sleep in their closed shells, or the shellless slugs adhering to roots protected from frost in warm cavities or cellars. Whether the production of *D. hepaticum* in the human liver may take place by drinking impure water, must remain quite undecided. The finding of a young *Distomum* in the sole of a woman's foot appears to be in favour of an immigration, and a mode of existence similar to the *Cercaria*.—(Op. cit., p. 270. 1.)

wormwood, with the addition of aloes; and many administer clysters of salt water, or a solution of salt in water with olive or castor oil. When the patient is distressed by these parasites during the night these or similar enemata should be administered at bed-time or shortly before. Numerous preparations of the santonicum, and various combinations of this seed with other substances, as the powder (3j.—3ij.), the infusion, the decoction, the extract—in the form of electuary, mixture, confection, bolus, &c.—with valerian, or jalap, or calomel, or aloes, or rhubarb, or sulphate of potash, or with sulphate of iron, or with alkaline carbonates, are contained in the Continental pharmacopœiæ, and employed against this and other species of worms.

198. The means which I have usually employed, for many years, against the *Oxyuris vermicularis*, with the view not merely of removing them, but also of preventing their regeneration, and of improving the functions of the bowels and the state of the general health, are combinations of preparations of iron with those of aloes, taken internally for some days, or even weeks, according to their effects; and afterward enemata with olive or castor oil, spirit of turpentine, or asafetida, camphor, salt, &c., in gruel, according to the peculiarities of the case. The mist. ferri may thus be conjoined with the decoctum aloes compos., or with the tinct. aloes; or the pilula ferri comp., or sulph. ferri, may be given with the pilula aloes cum myrrha, the pilula galbani comp. and camphor. Electuaries may also be prescribed in other cases, with the carbonates or oxides of iron, the santonicum and confection of senna, with a small proportion of the confection of black pepper; and, if these do not completely remove the annoyance, the use of the enemata already recommended should be adopted (see FORM. 71, 80, 105, 106, 149, 151, and 153). In some cases where these are required, the long flexible tube should be introduced above the sigmoid flexure of the colon, so that the remedies may reach above this part of the bowel. Having removed the worms, it will be of service, in order to prevent their regeneration, to continue the use of the preparations of iron in conjunction with aperients and the other medicines which the circumstances of the case will suggest. The following pills have been found by me, for many years, to be most successful in removing and in preventing the regeneration of the *oxyuris vermicularis* and the *ascarides lumbricoides*, both of which parasites are often present in the same case:

No. 394. R Ferri Sulphatis; Quinæ Sulphatis; Camphoræ, aa, gr. xvj.; Pilulæ Galbani Comp., ʒijss.; Pilulæ Aloës cum Myrrha, ʒj.; Pulv. Capsici, gr. xvj.; Olei Cajuputi, ℥xxx.; Mucilag. Acaciæ, q. s. Misce, contunde bene, et divide in pilulas xxxvj., quarum capiat unam, duas, vel tres, bis terve in die.

The aloes, in combination with sulphate of quinæ, acts energetically on the bowels; therefore the dose of these pills should be regulated according to their operation—a larger dose being given for the expulsion of the different species of ascarides; and the smaller doses for the prevention of their regeneration. The enemata already recommended should also be administered after the pills have been taken during two, three, or five days, the repeated exhibition of these latter rendering the former more efficient and generally successful.

199. E. The *Strongylus gigas* (§ 128–130).—

This worm, which is found chiefly in the kidneys and urinary bladder, can hardly be inferred to exist during life unless its discharge takes place, which very rarely occurs. KÜCHENMEISTER remarks that if several worms, or one large female, be present, the kidneys will be enlarged, so that the enlargement may be detected by palpation, percussion, and perhaps by inspection; but the cause of this swelling, or any flow of blood from the urinary passages, or of any existing retention of urine, could be referred to the presence of these worms only when any of them are passed from the bladder; and in this case the treatment would be chiefly to alleviate irritation by mucilaginous and oily medicines, and emollients, demulcents, &c. The oil of turpentine internally and externally may probably be of use in some instances.

200. F. The *Ancylostomum duodenale* (§ 132–135) is one of the inflictions on Egypt and some other tropical countries, and to GRIESINGER we are indebted for all we know respecting it. Unacquainted at first with the real cause of the disease which it occasions—with the prevalent anæmia, chlorosis, &c., produced by it—he had prescribed iron, quinine, calcarea phosphorica (phosphate of lime?), &c., with much benefit in slight cases, but never with complete success in those which were severe. KÜCHENMEISTER states that in one of his last dissections a sudden light broke in upon him on this subject, when he found the duodenum, the jejunum, and even the upper half of the ileum, entirely filled with fresh red blood, only coagulated here and there, and thousands of *Ancylostoma* on the mucous membrane of the small intestine, each with its little ecchymosis resembling the bite of a leech. Although he thus left Egypt, and could collect no farther clinical observations, he told the Arabian prosecutor, “You must now employ calomel and other anthelmintics against these *Ancylostoma* and the *Distoma* of the portal vein; in short, against the tropical chlorosis, as well as against hæmaturia, stone, dysentery, abscess of the liver, and all the undetermined diseases of tropical countries, perhaps even some of the tropical fevers, and investigate the latter illness itself, with reference to the most recent helminthological discoveries.” Above all things, GRIESINGER praises calomel and oil of turpentine *à priori*, the latter, indeed, especially for the *Distoma* of the portal vein, above all for the *Ancylostoma*, as it certainly reaches the worms situated in the uppermost parts of the intestine; in substance, worms die in it very readily, and it also acts as a styptic upon the injured, bleeding vessels. This last remedy, when mixed with castor-oil, or with castor-oil and a few grains of santonine, or the *natron santonicum*, to which vegetable purgatives are added, must prove particularly efficacious. “None of our colleagues working in the tropics should forget that tropical chlorosis is the consequence of the repeated, small intestinal bleedings, which scarcely betray themselves externally, caused by intestinal worms, especially *Ancylostoma*.”

201. G. The *Filaria Medinensis* (§ 138–142). —a. The prevention of this worm may be inferred from the causes and circumstances connected with its occurrence, namely, the endemic prevalence of filaria in certain climates and localities, its youngest brood living free in the water, or in wet grass, marshes, or moist soil, &c. Hence,

wading through these places with naked feet, or exposing naked parts of the body to foul or impure water, should be avoided as sources from whence the brood comes in contact with these parts in the native countries of this worm. PRUNER states that an infection of the filaria may occur, as shown by numerous facts, even in those tropical regions in which the worm is not endemic, an actual transfer from one person to another or to dogs and horses taking place. BREMER says that even in his time the worm had become naturalized in Curaçoa by the importation of negroes. No one, therefore, should use the same vessels employed by the patient in bathing or washing the feet; and that great caution should be observed with the bandages of such patients.

202. *b. Curative Treatment.*—At the commencement of its growth, this worm is said, when superficial, to be easily killed by poultices of boiled garlic. When quite superficial, an incision is made upon it, and the worm pulled out with a hook. Slave-dealers rub in civet and musk on its first appearance. But the worm often produces no annoyance for a long time—six to eight months. When it inflames and ulcerates the integuments over its seat, the part which appears is seized, and carefully pulled and fastened to a roll of linen or stick, and gradually extracted by turning these twice daily. Some writers advise, when the worm is felt, to cut down through the integuments, making an incision of several inches long, and removing the worm in a loop, or wedging into a piece of wood, and then pulling now on one side and now on the other, the muscles being all the while relaxed. If inflammation, swelling, and pain are great, and the worm resists dragging, or breaks off, these symptoms are to be treated in the usual way, by poultices of linseed meal, or of onions and bread, or onions boiled in milk, or of roasted onions, &c. In these cases numerous means have been recommended in addition, but none of them appear very appropriate or successful.

203. From the most ancient periods the breaking of the worm has been considered a very serious accident; and severe inflammation, fever, gangrene, &c., have been, even by some modern writers, said to have resulted from it. According to the observations of most authors, who had themselves suffered from the breaking of the worms, violent swelling, inflammation, fever, sleeplessness had occurred, and were cured only when they were killed. The diagnosis in cases of *Filaria medinensis* should always be correctly made, in order to determine the presence of this worm, and to distinguish between *FURUNCULI* (see that article) and inflammatory swellings caused by it.

204. *II. The Treatment of Ascaris Lumbricoides* (§ 141–149).—*a.* For the prevention of this worm it is necessary to bear in mind the circumstances in which the eggs may occur, and the long period during which they may be preserved. RICHTER ascertained that the eggs may remain in sewerage and foul water for some time, and that they attain their full maturity, and undergo the process of segmentation in this situation. BARRY, BISCHOFF, and others have shown that alkalies and salts do not prevent this process. VERLOREN, that a period of eleven or twelve months is required for the completion of this process in the *Ascaris lumbricoides*. RICHTER and KÜCHENMEISTER state that eggs which had been put in

water had not shown any appearance of embryos several months afterward. As to what becomes of the ready-formed embryos nothing is known positively; they probably get into our bodies with water, and perhaps this is sufficient for their development.

205. *b. The Cure of Ascaris Lumbricoides*.—The number of medicines recommended with this object are so great that the judgment is distracted respecting them. In order to assist the selection, it has been attempted to determine the effects of the most reputed vermifuges upon living intestinal worms from recently-killed domestic animals, by REDI, ANDRY, LECLERC, TORTI, ARNEHMANN, CIABERT, and others. More lately, KÜCHENMEISTER has had recourse to similar experiments made in the temperature of the animal, by mixing the anthelmintic in white of egg, and placing the living worm in the mixture, and has given us the following results, “arranged according to the time in which round worms died in white of egg mixed with the various remedies.

206. “1. Death took place in one to two hours in white of egg mixed with creasote, and large doses of common salt and corrosive sublimate.

207. “2. Death took place in two to five hours in white of egg mixed with petroleum, cajuput-oil, oil of turpentine, mustard, weaker solutions of common salt, and washed herring’s milt.

208. “3. Death took place in five to fifteen hours in white of egg mixed with garlic, onions, laurel, cloves, wood vinegar, rad. jun. granati, tinct. gallarum, concentr. sol. of sulph soda.

209. “4. Death took place in fifteen to twenty-four hours in white of egg mixed with camphor, anise, and infusions or decoctions of ginger, gentian, elm-bark, koussou, and hops.

210. “5. Death took place after twenty-four hours in white of egg mixed with infusion or decoction of parsley, rice, milfoil, tansy, valerian, chamomile, wormwood, myrrha, quassia, calamus, ipecacuanha, walnuts, china-bark, willow-bark, oak-bark, catechu, kino, asafoetida, gum ammoniac, Peruvian balsam, ol. ricini, aqua picis, creasote water,” &c.

211. This writer states that besides the remedies here enumerated he has tested the *semina cinæ* (*santonici*) with their preparations. In a mixture of white of egg with coarsely-powdered seeds the worms live for days; and in a mixture of white of egg with a strong infusion of *semina cinæ*, with repeated additions of unboiled powder, they also lived for days. In a mixture of *santonine* with water and white of egg, the worms lived for days; and also in white of egg with *santonine* and a little vinegar. At the same time, however, the total insolubility of the *santonine* was proved by farther experiments. In white of eggs mixed with castor-oil and *santonine* the worms died within an hour; but in this experiment the temperature was raised too high. In a mixture of white of egg with *natron santonicum* (*santonate of soda*) dissolved in water, *ascarides* lived more than twelve hours. These experiments form an introduction to the treatment advised for *Ascaris lumbricoides* by KÜCHENMEISTER, and more especially to the use of the preparations of *santonine*; but he previously notices the employment of the *semina santonici* by other helminthologists, who generally prescribed this remedy in the form of an electuary.

212. (*a*) *Storck’s Formula*:

No. 395. R Pulv. Semin. Santonici (vel Cinæ), ʒij.;

Rad. Valerianæ Min. Pulv., ʒj.; Rad. Jalapæ Pulv., ʒss.; Oxytellis Scill., q. s. ut fiat electuarium molle.

One tea-spoonful every three hours.

213. (b) SELLE'S Tonic Worm Electuary:

No. 396. R Pulv. Seminum Cinæ, ʒvj.; Ferri-Sulph. Cryst., Extr. Chloæ Fuscæ, āā, ʒij.; Syrupi Cinnam., q. s. ut fiat electuarium molle.

One tea-spoonful three times a day. This electuary is to be preferred some time after the expulsion of *Ascarides*, and to ascertain their permanent removal.

214. (c) HUFELAND'S Worm Electuary:

No. 397. R Pulv. Sem. Santonici, ʒss.; Pulv. Rad. Jalapæ, ʒj.; Kali Tartar. depur., ʒij.; Pulv. Rad. Valerianæ, ʒss.; Oxytel. Scillæ, ʒvj.; Syrupi Simp., q. s. ut fiat electuarium molle.

One tea-spoonful every two or three hours.

215. (d) CLARUS and other German physicians advised the Semin. Santonici, coarsely powdered, to be sprinkled over bread, and spreading sirup of honey over the powder, administering from ʒss. to ʒj. several times a day in this manner, followed every third or fourth day by a purgative.

216. (e) BREMSER'S Electuary:

No. 398. R Seminum Santonici vel Tanacetii Vulgaris ruditer contusum, ʒss.; Pulv. Rad. Valerianæ, ʒij.; Pulv. Rad. Jalapæ, ʒjss.—ij.; Tart. Vitriol. (Potassæ Sulph.), ʒss.—ʒij.; Oxytel. Scillæ, q. s. ut fiat electuarium molle.

A tea-spoonful to be taken two or three times a day. After taking two tea-spoonfuls daily for three or four days, slime and worms pass off with more copious stools. If the worms are not expelled, BREMSER administers some more of the electuary twice or thrice. If the first pot of electuary be insufficient, a second is taken, but watery stools must not be produced. He never allowed more than two potfuls to be taken; and he considered it unimportant whether worms passed or did not pass during its use. To relax the bowels once in the midst of this treatment he prescribed the following:

No. 399. R Pulv. Rad. Jalapæ, ʒj.; Pulv. Fol. Sennæ, ʒss.; Potassæ Sulph., ʒj. Miscæ. Fiat pulvis in partes iij. vel. iv. æq. divid.

Half a powder to be taken every half, or every hour, or two hours, until it operates. For leucophlegmatic subjects he often gave CHABERT'S oil (composed chiefly of turpentine rendered still more nauseous), in doses of two tea-spoonfuls in water, night and morning.

217. The Semina Santonici, KÜCHENMEISTER states, have been recently displaced by the preparations obtained from them, and in his opinion with justice. He extols chiefly two of them, viz., Santonine and the Santonate of Soda; all the rest being unnecessary. He considers it to be preferable to administer santonine with fatty oils, in order to bring it into solution as readily as possible; and for this purpose he prefers to give it sprinkled upon bread and butter, or in the yolk of an egg with sugar; and afterward to follow it every three or four days with a gentle purgative (jalap or confection of senna), or to administer it in castor-oil—gr. ij. to iv. of the santonine\* in ʒj. of the oil, to be taken in tea-spoonfuls until

purgative action commences. In this way the remedy should be repeated, if possible, for some days, or every other day, so that soft stools, rather than actual purging, should be passed. Milk and butter-milk may be taken during this treatment. "Among the santonine lozenges, those prepared from cocoa, undeprived of oil, are most deserving praise." KÜCHENMEISTER remarks that the most troublesome effects of this remedy are spasms, obstructions, with tenesmus, and even bloody stools; but that with a careful employment of the remedy (gr. ij. to iv. with ʒj. of castor-oil) he has never seen ill effects produced by it, the administration of it with castor-oil always preventing intestinal obstructions. The most annoying symptom, to the patient only, is the yellow or blue, or even green appearance of objects, owing probably to the effect of this remedy on the nervous system; but this appears to be only a temporary inconvenience, which soon disappears after the discontinuance of the remedy. This writer adds that "it follows, as a matter of course, to be cautious in the use of santonine, that he would never give more than eight grains of it in two days, divided into doses of two grains each twice a day, and that, on the second day of its use, he would administer an aperient."

218. (f) The Santonate of Soda.—Natron santonicum has recently been greatly praised by H. E. RICHTER and KÜCHENMEISTER, for its successful action in cases of *Ascaris lumbricoides*. The latter of these physicians states that he has never seen injurious effects from this medicine, even when administered in doses of eight to ten grains twice a day to adults. "The remedy to be given alone, as every acid decomposes it, and it must not be mixed in electuaries." He adopts nearly the following method: He lets children (or adults) take a powder of santonate of soda with sugar (from two to six grains) on a Friday night, and he repeats the same dose on Saturday morning (fasting) and evening, and again on Sunday morning. On Sunday, half an hour or an hour after the last powder, an aperient electuary (confectio sennæ, &c.), or a sufficient dose of jalap, is taken, so that several soft motions may follow. By these means the worms usually pass off alive; or they wander forth singly afterward, and without stools, their residence having become disagreeable to them. Dr. PÖCKELS, who noticed a blackish discoloration of the tongue after santonine, praises, as a remedy for *Ascaris lumbricoides*, the root of *Aspidium filix mas* in conjunction with purgatives.

219. (g) I have found no remedies more efficacious for the *Ascaris lumbricoides* than turpentine, as prescribed above (§ 183–185) and in Form. 216, and the infusion of *spigelia* and *santonicus*, as directed in Form. 264 in the APPENDIX. For this worm, also, as well as for the *Oxyuris vermicularis*, the preparations of the semina santonici, prescribed in the APPENDIX, will also be found successful. (See Formula 71, 80, 105, and 106.) These and other medicines will be frequently as successful without as with the preliminary treatment recommended by the German writers; the exact operation of such treatment often being not very manifest. The great success derived from the powder and tincture of kamala, in India, in the treatment of tape-worms (see § 190–193), and the effects of this substance upon these worms, promise similar results from it, if it were prescribed against the *Ascaris lumbricoides* and the *Oxyuris vermicularis*.

\* The preparation of santonine is best effected by the employment of ammonia. It must be tasteless, when pure, because it does not dissolve in the mouth. Dissolved in alcohol, it is bitter. It is sparingly soluble in warm water, but is readily in oils. It is inodorous, has a slight acid reaction, combines readily with alkalies, and becomes yellow in the light of the sun. When impure, it still contains resins and essential oils, and is consequently nauseous to the taste.—(CALLOND, in *Pharmacie Centralblatt*, 1849, p. 413; and J. CLARUS, in *Handbuch der Speziellen Arzneimittelehre*, 1852, p. 333.)

[One of the best remedies against worms is the *Absinthum* (wormwood) tincture, wine infusion, or essential oil. The tincture, made by adding one part of wormwood to eight of proof spirit, is powerfully tonic, stomachic, and anthelmintic, and may be given in doses of from one fluid scruple to two fluid drachms three times a day; or 2 parts wormwood to 50 of wine, digested and filtered, may be used in 2 or 3 drachm doses, several times a day. This is a very useful remedy as a corroborative and preventive, after the removal of worms. An excellent anthelmintic may be prepared after the following formula:  $\mathcal{R}$  Seeds of artemisia, extr. of tansy, each six grains; oxyde of iron, four grains; oil of valerian, one drop. *M.* The following, though disagreeable, is very efficient:  $\mathcal{R}$  Black oxyde of iron, 3ss.; asafetida, 3jss.; oil of tansy, gtt. x.; extr. of wormwood, q. s. *M.* Divide into 90 pills; six three times a day. The *chénopodium* is a safe and effectual vermifuge, used after the following formula:  $\mathcal{R}$  Fresh leaves, 5j.; new milk, Oj.; orange peel, 3ij. Boil and strain. Dose, a wine-glassful twice a day.— $\mathcal{R}$  Oil of worm-seed, 3j.; sugar, gum Arabic, each 3jss.; mix, and add mint-water, 5jss. Dose, a tea-spoonful four times a day, for two or three days, to be followed by a purge. In cases of lumbrici, the following will be found very successful:  $\mathcal{R}$  Cowhage, 3j.; sirup, 5ss.; mix. A tea-spoonful every morning, fasting, for three days, to be followed by oil; or,  $\mathcal{R}$  Cowhage, 3j.; honey, sufficient to make electuary, given as above. The following vermifuge emulsion is a pleasant and successful remedy for lumbrici:  $\mathcal{R}$  Castor-oil, mucilage of gum Arabic, each, 5j.; sirup of Corsica moss, water of lemon, contra-chamomile, each, f. 5ij.; emulsion of sweet almonds, f. 5viij. Mix. For tape-worm, a mixture of one ounce of castor-oil and two drachms of sulph. ether, in doses of a spoonful every two hours, is very efficient. Of the *spigelia* (pink-root) the following formulæ will be found useful:  $\mathcal{R}$  Powdered pink-root, grs. x.; calomel, grs. iv. *Mix.* Take morning and evening, and, after four doses, a cathartic of castor-oil.— $\mathcal{R}$  Powdered pink-root, senna, each, 5ij.; savin, grs. xij. *M.* One every morning for three days, followed by a purgative.— $\mathcal{R}$  Pink-root, 5ss.; boiling water, Oj.; macerate for two hours in a covered vessel, and strain. 4 fl. drachms to one fl. 5, to children; 4 to 8 f. 5 to adults, morning and evening, followed by a purgative.— $\mathcal{R}$  Pink-root, 5ss.; senna, 3ij.; manna, 5j.; fennel-seed, 3ij.—5ss.; boiling water, Oj. Infuse. Half a wine-glassful to a child two years old, 3 times a day.— $\mathcal{R}$  Pink-root, 5j.; bruised rhubarb, 3j.; senna, 3ij.; semen contra, 3j.; manna, 3ij.; coriander, 3ss.; boiling water, Oj. Infuse. A small tea-cupful 3 times a day. Besides these, the simple fluid extract of pink-root, prepared by displacement, and the compound fluid extract, prepared in the same manner from pink, senna, savin, manna, sugar, alcohol, and water, will be found extremely convenient and efficacious in tea-spoonful doses 3 times a day, to young children, followed by oil. TILDEN'S fluid extract of pink and senna is a very successful preparation.

For ascarides, one of the most successful remedies is an *infusion of tansy*, as an injection, in the proportion of one ounce of the fresh leaves to one pint of boiling water. The *oil of tansy* is very effectual against the lumbricoid worm also, as in the following formula:  $\mathcal{R}$  Oil of tansy, one scruple; extract of gentian, two drachms; pow-

dered marsh-mallows, sufficient. Mix, and make 60 pills; 3 to 5 every two hours. The following is equally efficient:  $\mathcal{R}$  Tansy, 5j.; wormwood, rhubarb, each, 5ij.; sherry wine, f. 5ij.; diluted alcohol, fl. 5xx. Digest for eight days, and filter. Dose, f. 5j.—f. 5ij., 2 or 3 times a day. Also, the extract of tansy in doses of from 6 to 20 grs. three times a day.

Of the *purgative* anthelmintics, the following are some of the best:  $\mathcal{R}$  Powdered gamboge, grs. ij.; sulphate of iron, grs. vj.; sugar, 5j.; oil of peppermint, gtt. iij. Mix. To be taken twice a day against tape and lumbricoid worms.— $\mathcal{R}$  Calomel, grs. iij.; compound powder of scammony, grs. xii. For a dose for lumbrici.— $\mathcal{R}$  Calomel, grs. iv.; powdered pink-root, grs. x. To be taken two mornings in succession, also on afternoon of second day, followed by a mild purgative, for children over 4 years of age. As a fortifying tincture to prevent the recurrence of worms, equal parts of the muriated tincture of iron and tincture of aloes, in doses of 20 drops three times a day, will prove very effectual; or powdered sulphate of iron and aloes may be used in small doses.]

220. iv. AFTER-TREATMENT OF WORMS.—It is often requisite, after the expulsion of intestinal worms has been effected, 1st. To soothe the irritation, and to subdue the inflammatory action produced in the digestive mucous membrane by the vermifuges and drastic purges which had been prescribed. 2d. To remove any stray worms which had become so sickened, or so injured by the treatment, as to be readily thrown off by means which would restore the vital tone of the bowels and farther injure the worms, and render their residence disagreeable or untenable. And, 3d. To prevent the regeneration of these parasites by removing their ova and rendering the digestive mucous surface ungenial to their development. (a) The first of these intentions is best accomplished by emollients and demulcents with small doses of nitrate of potash, of hydrocyanic acid, and sirup of poppies, &c. When sickness is troublesome, and no inflammatory action is present, a pill with half a drop of creasote may be given with each dose of the above, or may be taken in the intervals between each. The diet should be spare, light, and digestible, and the bowels assisted by gentle laxatives, such as magnesia, with or without confection of senna, and by suitable enemata, especially by such as contain castor or olive oil, with oil of turpentine when the irritation is chiefly experienced in the stomach and upper portions of the intestinal canal; at the same time, the warm bath or terebinthinate embrocations, or a recourse to these latter upon leaving the bath, will be found of much service. The drink of the patient should be demulcent, and in small quantity, thirst in these cases being most relieved by sucking small morsels of ice.

221. (b) The second intention presupposes either the non-existence or the removal of those conditions against which the first intention was directed, and consists in the occasional exhibition of a moderate or less irritating dose or doses of the anthelmintic suitable to the expulsion of the worm found to be present, and the combination of it with such other means as the peculiar features of the case will suggest; a recourse to vermifuge clysters, especially to those already suggested, or those advised above (§ 194). being had after the internal remedies had been taken.

222. (c) The third intention is of no small im-

portance, if the permanent cure of the patient be considered. For the original conformation, or the depression of vital power, of the patient; or the irritability and exhaustion of the digestive canal may be so great, in consequence both of the existence of these parasites and of the means taken to expel them, that a tonic and restorative treatment becomes imperative in order to prevent various unpleasant contingencies. Besides, in many instances, anæmia has become so considerable as to require a treatment directed more or less to it, and to the other morbid tendencies. In these circumstances not only should due care be directed to the prevention of intestinal worms, but recourse should be had to those medicines which are calculated to restore the vital tone of the digestive organs, to improve the state of the secretions and excretions of the body generally, but of the intestines in particular, to promote the functions and actions of the bowels, and to render the human intestinal canal an unsuitable and an uncongenial habitation for the ova of worms and for their development. These are objects which should always be entertained after the expulsion of worms of whatever species, and should be attempted by such means as are most likely to accomplish them. It may be asked, however, where are we to find, how are we to combine these means, and how are we to prevail on the patient to persevere in their use, or even to have recourse to them when he believes himself free from his enemy? I cannot say that there are no other means calculated to attain these objects, but I may enumerate\* those which I have employed with these views, combining them variously, and exhibiting them in such successions, intervals, &c., and as the circumstances of particular cases appeared to require. The medicines which I have thus employed are the preparations of iron, asafetida, of cinchona and quina, of myrrh, camphor, aloes, infusions of willow, cascarrilla, and cedar bark, berberine, &c. The compound mixture of iron may be given with the decoction or tincture of aloes, &c.; or the sulphate of iron may be prescribed with sulphate of quina, compound galbanum pill, and with the aloes and myrrh pill. Camphor may be conjoined with these latter substances (§ 198) singly or in the combination now stated. The sulphate of quina may be given with dilute sulphuric acid, and sulphuric ether. The infusions of the barks may be taken with tonic and laxative tinctures, or with the mineral acids, &c., and laxative electuaries may be conjoined with sulphur, or antispasmodics, aromatics, or spices.

223. It is obvious that the diet of patients who have suffered from worms should be nutritious, digestible, and restorative; while it ought not to be too rich or full, or calculated to produce general plethora or local congestions, as of the liver, &c. The regimen ought to be regulated so that suf-

ficient exercise may be taken in the open air, and that all causes of debility and exhaustion should be avoided. The remarks already offered for the prevention of the human entozoa (§ 157, *et seq.*) are equally necessary to the prevention of their return after their expulsion.

\* I may here state that the pharmacopœia of the United Kingdoms are very deficient in vermifuge remedies, and in formulae for the preparation and combination of them—a remark by no means applicable to the pharmacopœia of most Continental countries. But verminous diseases are much more prevalent on the Continent than in the British Isles, in which, however, I am confident that their prevalence has hitherto been much underrated, and their importance undervalued. The very general and noxious vice of smoking tobacco, and of otherwise using this poison—so much extended in recent times—has rendered, and will still more render, verminous diseases more prevalent, by weakening the digestive organs, and disposing them to the generation and development of the ova of worms.

Schilling*, Case of Cysticercus cellulosa, with Remarks, New York Journ. of Medicine, March, 1857, vol. ii, N.S., p. 194. (This was a case of a female aged thirty-one years, who was affected with epilepsy, severe headaches, and stupidity, who died suddenly during an epileptic seizure. Autopsical examination revealed several hundred cysticerci adherent to the inner surface of the dura mater and the surface of the

brain itself, of the size of a pea, suspended by a pedicle from the membrane, or lying free upon and between the cerebral convolutions, and even the substance of the brain and choroid plexus. Five were found in the muscles of the heart; several were found in the gluteal and deltoid muscles. No traces of tæniæ were found in the intestines. Dr. S. relates also the history of another case, a German emigrant, who was seized with dizziness and headache, followed by fatal hemiplegia. The autopsy revealed a cerebral abscess, in which was found a shriveled-up *cysticercus cellulosæ*.—H. Bigelow, Case of Worm discharged from an Abscess, *ibid.*, vol. xxxiii., p. 486; *ibid.*, vol. iv., p. 179, 194, on the Production of Intestinal Worms, by the Editor; also vol. vii., p. 291. Journal*, Jan., 1826.—Filaria in the Eyes of Horses in the East, *Bulletin des Sciences Medicales*, Feb., 1826.]

YAWS. See VENEREAL DISEASES (§ 85, *et seq.*).

ZYMOTIC DISEASES.—Ζυμωτικός, causing to ferment; ζύμωσις, a fermentation; ήπατος ζύμωσις, a swelling of the liver, HIPPOCRATES. The term *Zymotic* has recently been applied by Dr. FARR to epidemic, endemic, infectious, and contagious diseases, and has comprised small-pox, measles, scarlatina, hooping-cough, croup, thrush, diarrhœa, dysentery, cholera, influenza, ague, remittent fever, typhus, erysipelas, syphilis, hydrophobia. Viewing the Greek term to mean a leaven by which the organic nervous system, or the vascular system and blood, may be infected or contaminated either successively or contemporaneously, or nearly so, the term well designates an extensive class of diseases, although its application implies a hypothesis; but it is well suited to the arrangement adopted by Dr. FARR in his admirable Annual Reports of Deaths, &c., in England (which see).

## SUPPLEMENT.

SUPRA-RENAL BODIES. — SYNON. — *Glandulæ ad Plexum, Glandulæ ad Plexum Nervium*, T. WHARTON. *Glandulæ supra-renales, Renes Succenturiati*, Auct. *Supra-renal glands, Supra-renal capsules, &c.*

1. I. STRUCTURE AND FUNCTIONS.—In the present state of our knowledge the name "*supra-renal bodies*," or that adopted by WHARTON, appears more correct than supra-renal glands, the functions of glands not having been proved in respect of them; and the term capsules is equally inapplicable, even to their more external structure. Succenturiati, or reserved kidneys or bodies, are not less appropriate. The earliest notice of the connexions and nature of these bodies appears to have been taken by WHARTON, who pointed out their relations to the ganglial nerves, as remarked by Dr. GULL. Nevertheless the functions and diseases of these bodies received no attention from physiologists and pathologists (although in several instances organic lesions observed in them had been published in the *Ephemerides Naturæ Curiosorum*, and more recently by VETTER and BAILLIE) until very lately, when the structure and functions of these bodies were remarked upon by NAGEL, BERGMANN, ECKER, KÖLLIKER, LEYDIG, and GREY; and their diseases, especially in connexion with a bronzed discoloration of the skin, were first investigated by Dr. ADDISON, and subsequently by Mr. HUTCHINSON and others. It is chiefly, however, to Dr. ADDISON that the distinction of having first directed attention to these lesions is due. Although several cases have been recently observed and recorded—not always, however, with due care and precision—still the number of those in which a bronzed state of skin appeared more or less intimately connected with, and most probably caused by, disease of these bodies, is so great as to induce a presumption that where the former appearance exists the latter lesion will be found. In order, however, to form correct views as to the phenomena by which diseases of the supra-bodies are indicated, as well as to the nature and consequences of such disease, it becomes requisite that we should previously briefly inquire into what is known of the structure and functions of these bodies. Unfortunately opinions on these topics have been, and, notwithstanding the frequency of microscopic research in modern times respecting them, still continue to be, very unsatisfactory. Dr. WHARTON, about the middle of the 17th century, first noticed their connexions with the ganglia of the solar plexus, and suggested a name for them, which appears more appropriate than any other which has more recently been given them.

2. I. STRUCTURE.—KÖLLIKER has very recently described the microscopic appearances of these bodies, and noticed what appears to be their func-

tions, and Dr. HARLEY has still more recently examined their structure.—A. The *cortical structure* of these bodies is described by the latter observer as consisting of cells, arranged in irregularly-sized rows, in a fibro-areolar matrix, the rows of cells appearing like a number of dark-yellow columns placed perpendicularly to the surface. The cells, when examined individually, seem to be composed of a homogeneous cell-wall, filled with granules, pigment, and some fat globules. Each cell has a well-marked nucleus, although not always visible. The cells are arranged in a number of larger and smaller masses, which are placed in regular rows, and thus give rise to the columnar appearance. In some cases a column is composed of several cell-masses of different lengths, placed end to end; in others it consists almost entirely of one long cell-mass. Each column, as well as each cell-mass, is separated from the others by delicate fibrous tissue, in which are included the vessels and nerves. Sometimes the cell-masses present the appearance of long tubes, enclosing a single straight row of quadrilateral cells. Each cell-mass is closed at the extremities, and is surrounded by a delicate homogeneous membrane.

3. B. The *medullary substance*, according to KÖLLIKER, also has a *stroma* of connective tissue, which, prolonged from the cortical lamellæ, pervades the whole interior, for the most part, in more delicate fasciculi, constituting a net-work with narrow, rounded meshes. In this net-work lies a pale, fine-granular substance in which, in man, and in recent preparations, pale cells of 0.008 to 0.16" are generally observed. These pale cells occasionally present, in their fine-granular contents, a few fat or pigment granules; their frequently very distinct *nucleus* with large *nucleoli*, their angular form, and occasionally their single or multiple, or even branched processes, resembling the nerve-cells of the central organs, although they cannot definitively be declared to be such. Dr. HARLEY states that the dark slate-coloured medullary substance is composed of a net-work of fibres, in the meshes of which are a number of large nucleated cells, which have been described by various writers as ganglion corpuscles; but he thinks that these, like the cells in the cortical substance, are true secreting cells. This great difference of opinion (so frequently observed among microscopists)—the same nucleated cells being considered as ganglial corpuscles by some observers, and as true secreting cells by others—prevents, in the present state of our knowledge, much reliance to be placed upon the results of microscopic researches, each successive observer being liable to the distrust which attaches itself to his predecessors. However, the following is less liable to objection:

4. C. The *nerves* of the supra-renal bodies are, according to BERGMANN and KÖLLIKER, extreme-

ly numerous; arising, according to them, from the semilunar ganglion and renal plexus, and to a small extent from the vagus and phrenic nerves; but most probably intercommunicating with, rather than arising from, the latter. In man, KÖLLIKER counted in the right supra-renal body thirty-three trunks, eight of which were 1.5 to 1.10''; five of 1.14 to 1.20''; seven of 1.25 to 1.33''; and thirteen of 1.45 to 1.50''; and found that without exception, or at all events in a very preponderating proportion, they were constituted of dark bordered, finer and medium-sized, or even thick fibres; were whitish or white, and furnished with isolated larger or smaller ganglia. They are especially apparent on the inferior half and inner border of the organ, and appear to be all destined for the medullary substance, in which, at least in the mammalia, an *extremely rich plexus* of dark-bordered, finer fibres occurs, enclosed in the *trabeculae* and connective tissue, their terminations, however, being nowhere perceptible.

5. ii. FUNCTIONS.—As regards the *functions* of the supra-renal glands, in the absence of all physiological indications, and so long as the course of the nerves in them is not more accurately known than at present, only very general observations can be offered. KÖLLIKER considers the *cortical and medullary substances as physiologically distinct*, and that the former may, provisionally, be placed with the so-termed "blood-vascular glands," and a relation to secretion assigned to it; while the latter, on account of its extremely abundant supply of nerves, must be regarded as an apparatus appertaining to the *nervous system*, in which the cellular elements and the nervous plexus either exert the same reciprocal action as they do in the gray nerve-substance, or stand in a relation as yet wholly unascertained towards each other.

6. According to LEVDIG, the *cortical substance* of the supra-renal capsules of the mammalia corresponds to the yellow, granular, and striped supra-renal bodies of fishes and amphibia; while the *medullary substance* of the mammalian organ, which is abundantly supplied with nerves and cells, very like the ganglion globules, represents the other divisions of the sympathetic ganglia: whence he concludes that BERGMANN'S view, according to which the supra-renal capsules are closely related to the nervous system, is undoubtedly correct, and that those organs bear the same relation to the ganglia of the sympathetic nerves as the pituitary body bears towards the brain. Besides this relation to the nervous system, however, they have an intimate one with the vascular; and are, therefore, always pervaded by a very close capillary plexus.

7. The functions of the supra-renal bodies have been *experimentally* investigated by BROWN-SÉQUARD, HARLEY, and others, but with different results. We know how uncertain these results are in the lower animals, and the amount of confidence which may be reposed in them, not only in those which were so frequently performed thirty and forty years since in order to determine the functions of distinct portions of the nervous system, but also in those more recently made with these and with other views. The former of the experimenters just named removed the supra-renal bodies from fifty-one rabbits, eleven adult cats and dogs, eleven young dogs and cats, eleven adult Guinea-pigs, four young Guinea-pigs, and two mice; and he states that the adult ani-

mals operated on died, on an average, in twelve hours, while the young or new-born animals lived thirty hours. From these experiments Dr. BROWN-SÉQUARD concludes that the supra-renal bodies are more necessary to life than even the kidneys; for animals will live two, or even three days, after the removal of the latter organs. Dr. HARLEY quotes from a later publication of Dr. BROWN, in which the latter states that, of ten rabbits from which he extirpated the supra-renal capsules, six died between the seventh and tenth hour, and four between the tenth and fourteenth hour after the operation, and adds, that the animals died too quickly to admit of their death being the result of peritonitis; and farther, that the extirpation of these capsules is followed by symptoms which do not occur after injuries of the peritoneum or liver, &c., these symptoms indicating that the supra-renal bodies have an important influence on the blood, and that their nerves have a singular power upon certain parts of the central nervous system. He states that this latter influence manifests itself very distinctly in some cases after the extirpation or the puncture of one of these bodies, the animals being sometimes seized a few minutes before death by vertigo and rolling over. Dr. BROWN-SÉQUARD concludes, 1st, "that if these organs are not essential to life, they are at least of very great importance. Secondly, that their functions appear to be at least as important as that of the kidneys, for when they are absent death in general supervenes more rapidly than after the removal of the kidneys." (*Archives Génér.*, 1857, p. 374.)

8. Dr. HARLEY has published experiments which furnish different results from those now stated; and from those he infers that "the supra-renal capsules are not absolutely essential to life;" that "the removal of the right is generally more fatal than the removal of the left capsule;" that "convulsions do not necessarily follow the removal of the capsules;" that, "when death follows upon the extirpation of the supra-renal bodies, it is in most cases in consequence of the injury done to the neighbouring tissues; perhaps more frequently the mutilation of the ganglionic system of nerves;" that "absence of the function of the supra-renal bodies is not proved to have any special effect in arresting the transformation of hæmatin or in increasing the formation of blood-crystals;" and that the suppression of the functions of these bodies is not attended by an increased deposit of pigment in the skin, or its appendages, in certain of the lower animals—the problem of the connexion of bronzed skin and supra-renal capsular disease being more likely to be solved in the dead-house than in the physiological laboratory.

9. Viewing the structure and connexions of the supra-renal bodies as altogether similar to those of the pituitary gland, and considering these organs as very intimately connected, anatomically and functionally, with the ganglia and ganglionic plexuses, I have been induced to view them as organs contributing or subsidiary to the organic nervous force or influence exerted by the ganglionic nervous system. Thirty-four years ago I published this opinion of the function of the pituitary gland in my *Physiological Notes*, &c. (in 1824), and stated that this gland reinforced the ganglionic nervous influence endowing the brain by means of the ganglionic nerves distributed to the cerebral organs—that it was a portion of the gan-

glial nervous system contributing to the nourishment and functions of the brain, *and imparting a unity of development, of permanent nutrition and of function, to the double organs composing the cerebral mass.* It appears very probable that similar offices are performed by the supra-renal bodies as regards the ganglia and ganglionic plexuses of the abdomen; these bodies contributing to the functions of the organic nervous or ganglionic system, as displayed by the abdominal organs—whether digestive, assimilative, or generative. That both the pituitary body and the supra-renal bodies perform these important functions—important not only as respects the performance of their respective functions, but also as regards the life of the individual—appears to be manifest from the nature and character of the nervous communications existing between them and other parts of the ganglionic nervous system; for, instead of describing these communications merely as branches of nerves detached from other ganglia or parts, it would be more correct, taking the size and appearance of these branches into consideration, to describe them as branches sent from the medullary structure of these bodies, to those ganglia, plexuses, and nervous trunks, in order to convey to these the special influences or functions of these bodies; or, otherwise, to reinforce and combine the influence exerted by these several ganglia and parts, with which they are anatomically connected. That these bodies are of the greatest vital as well as functional importance is evinced not only by the consequences following their structural lesions, and by the presumed nature of their functions, but also by the manner and the positions of their lodgments; both the pituitary and the supra-renal bodies being so located as to render them, in their respective situations, farther removed, and better protected from injury, and even from structural or other disease, than any other part of the animal organization.

10. II. STRUCTURAL DISEASE OF THE SUPRA-RENAL BODIES.—*Lesions of the Supra-renal Bodies, and their Associations, &c.*

CLASSIF.—IV. CLASS, I. ORDER (see Preface, &c.).

11. DEFINIT.—*General languor and debility, anæmia, feebleness of the heart's action, remarkable irritability of the stomach, frequent vomiting, and pain in the back and loins, often with a bronzed or dusky hue of the general surface, rapidly increasing exhaustion, emaciation, &c.*

12 Disease of the supra-renal bodies usually commences so gradually as not to admit of the patient's knowledge of the exact period at which he first began to experience loss of health or strength. It is almost always gradual in its early progress, although often rapid in its more advanced course. The slowness or rapidity of its progress must, in the present state of our knowledge, be attributed to the nature and extent of the organic lesion, to the circumstance of one or both bodies being affected, and to the nature and severity, local or constitutional, of the malady

with which structural change of these bodies is complicated.

13. i. *Symptoms.*—Generally the patient at first complains of weakness or more marked debility, of languor, and of indisposition to bodily and mental exertion. The appetite is impaired or lost; the pulse is soft, weak, and often frequent; the whites of the eyes are pearly; the body is sometimes more or less emaciated, or, if not emaciated, leuco-phlegmatic or cachectic, or discoloured, and generally anæmied. Uneasiness or pain, often severe, is referred to the region of the stomach, epigastrium, back, or loins. Nausea, sickness, retchings, and frequent vomitings often occur, especially as the prostration, anæmia, and discoloration of the skin advance. In some cases, complicated with disease of other organs, especially when such disease is acute or disorganizing, the discoloration may either be absent or overlooked. In other cases it is slight, or in patches, consisting of a murky hue; but in others it amounts to a bronzed tint, and is general over the whole surface, but is commonly most marked on the face, neck, superior extremities, penis, and scrotum, in the flexures of the axillæ and limbs, around the umbilicus, &c., varying in deepness from a dingy or smoky appearance to a chestnut-brown, or colour of a mulatto. In some cases patches of a lighter hue occur in various parts; and in many the discolouring may be remarked in some of the internal surfaces, the peritoneum, pleura, &c.

14. With the continuance and progress of disease, the languor, anæmia, loss of appetite, and feebleness of the heart's action are aggravated. The discoloration of skin becomes in some cases more marked, the commissures of the lips much darker, the pulse smaller and weaker, vomiting more frequent and urgent, and pain and weakness of the back and loins more complained of. At last the patient sinks and expires, after a period which is very indefinite, so that the disease may appear almost acute in some instances, and more or less chronic in others, most probably owing either to the severity of the disorganizing lesions affecting the supra-renal bodies, or to the nature of the complications characterizing particular cases.

15. Although lesions of these bodies are often uncomplicated with disease of any other organ—although no lesion or disorder of any important or vital part can be detected, in many cases, during the life of the patient, lesions of these bodies, and a peculiar anæmia, being the only or chief lesions found after death, very frequently accompanied with discoloration—yet they are often associated with other diseases, chiefly of a constitutional and cachectic nature, more especially with general or partial tuberculosis, with cancer, and with disease of the lungs, &c.

16. The following table of cases of disease of the supra-renal bodies comprises nearly all those which have been published up to this time. It is constructed according to that published by Mr. HURCHINSON; and to it I have added some recent cases.

No.	References.	Sex and Age.	Occupation.	Previous Health, &c.	Early Symptoms.	Bronzing of Skin—its Degree or Absence.
1.	Dr. Addison's Works, p. 9.	Male, 32..	Baker.....	No history. Skin white when in health.	Cough, followed by debility and bronzing of skin.	Colour of mules to: scrotum and penis darkest.
2.	<i>Ibid.</i> , p. 12....	Male, 35..	Tide-waiter. Exposed to weather.	Rheumatism eight years previously. Health generally good.	Acute attack of fever, followed by debility and bronzing of skin.	Dark olive-brown; also in lining of lips.
3.	<i>Ibid.</i> , p. 15....	Male, 26..	Carpenter. Married. Intemperate.	Very good until three months before the change of colour.	Pain in the back and right leg, followed by debility, wasting, and giddiness.	Dark olive-brown, deepened in patches.
4.	<i>Ibid.</i> , p. 19....	Male, 22..	Stonemason.	No history. Died soon after admission.	Pain in stomach, vomiting, the douloureux.	Face, axillæ, and hands of bronzed colour.
5.	<i>Ibid.</i> , page 23. (From Dr. Bright's Reports.)	Female, adult.	Not stated ..	No history.....	No history.....	Complexion very dark...
6.	<i>Ibid.</i> , p. 25....	Male.....	Barrister. Of middle age.	No history.....	No history.....	Surface generally dark; face, neck, and arms covered with deep brown patches.
7.	<i>Ibid.</i> , p. 30....	Female, 60	Not stated ..	No history. Cancer of supra-renal bodies; consecutive of cancer of breast.	Cancer of breast .....	Skin of arms, chest, and face of a light-brown colour.
8.	<i>Ibid.</i> , p. 32....	Female, 53	A servant. Single.	Always thin, but of good health.	Cutaneous eruption four months previously, its cure being followed by stomach symptoms.	Skin generally very dark, with darker patches.
9.	<i>Ibid.</i> , p. 35....	Male, 53..	Sailor. Married. Sober.	Very good. A strong muscular man.	Two months previously began to lose appetite and be generally unwell.	Face of a yellow bronzed tint, becoming still darker.
10.	<i>Ibid.</i> , p. 38....	Female, 28	Not stated ..	Died of cancer uteri. Disease of supra-renal bodies being consecutive.	Those of cancer uteri....	A peculiar dingy appearance.
11.	<i>Ibid.</i> , p. 39....	Male, adult.	Not stated ..	Died of cancer of lungs, &c.	Those of cancer of the thorax.	Face of a dingy hue, with freckles and brown discoloured spots.
12.	Med. Times & Gaz., Dec. 15, 1855. (Dr. Burrows.)	Male, 24..	Hawker. Single.	Had lumbar abscess in childhood.	Pain in the back, followed by emaciation and bronzing.	A dark copper or bronzed colour generally, and lighter patches.
13.	<i>Ibid.</i> , Jan. 19, 1856. (Dr. Gull.)	Male, 24..	Carpenter. Temperate.	Robust.....	Debility, breathlessness on exertion, nausea, &c.	Skin of a sallow olive-brown, darker on inside of lips, knees, &c.
14.	<i>Ibid.</i> , Jan. 19, 1856. (Mr. Bakewell.)	Male, 23..	Labourer ...	Not known.....	Not known .....	Skin generally dark brown or bronzed, and darker over the thighs.
15.	<i>Ibid.</i> , Feb. 20, 1856. (Dr. Thompson, &c.)	Male, 20..	Baker. Sober	Good.....	Bronzing of skin.....	Skin of a general peculiar dark dirty-brown colour.
16.	<i>Ibid.</i> , Feb. 28, 1856. (Dr. Rowe.)	Male, 20..	Not stated ..	Delicate.....	Delicate health and bronzing of skin.	Skin generally brown, with darker spots.
17.	<i>Ibid.</i> , March 8, 1856. (Dr. Parro.)	Male, 37..	A publican. Intemperate.	A year before had pain in the lumbar region, which subsided.	Admitted for delirium tremens.	Skin generally of a peculiar yellowish brown.
18.	Dr. Addison's Work, p. 29.	Male, 60..	Not stated ..	No history .....	No details .....	Generally dark and bronzed, with blanched patches.
19.	Med. Times & Gaz., p. 233. (Dr. Stocker.)	Male, 56..	Physician ..	Dyspeptic, but not otherwise ill.	General malaise and irritability of stomach, increasing debility and emaciation.	Patches of brown colour, which extended; small patches on the face.

General Symptoms, Complications, &c.	Duration of Disease.	Mode of Death.	Inspection after Death.	Remarks.
Excessive debility, emaciation, demeanour puerile, urine healthy, pain in lumbar region, cough, soreness at the epigastrium.	3 yrs.	Acute pericarditis and pneumonia.	Supra-renal bodies both remarkably indurated and as large as eggs, and quite disorganized; recent pericarditis and pneumonia; no tubercles nor other visceral disease.	A well-marked case. No chronic lesions but those of supra-renal bodies.
Pinched anxious expression, vomiting, pulse very feeble, depression, constipation, tenderness at epigastrium, numbness of extremities.	6 mo's	Not stated.....	Both supra-renal bodies contained compact fibrous concretions; gastric mucous surface inflamed; no tubercles; no other visceral disease.	The deposits in supra-renal bodies resembled tubercle, but there was no tubercle in other organs.
Thin, pale, and feeble; fainting on rising from bed, sickness and hiccough, pain in back, aug. curvature of spine, leucothymia, &c.	7 mo's	Passed into a torpid state.	Supra-renal bodies completely destroyed and converted into stumous deposits; psoas abscess and caries of lumbar vertebrae; tubercles in lungs; spleen enlarged.	The blood, both before and after death, contained a great excess of white corpuscles.
Vomiting and pain in stomach, great debility, emaciation, extreme prostration, &c.	Seve'l mon's.	From collapse and sinking.	Supra-renal bodies wasted and destroyed, both weighing only 49 grains. No other disease.	The disease of supra-renal bodies was an atrophy, probably consequent on inflammation.
Extreme debility, vomitings, emaciation, abscess in breast, &c.	Not stated.	Slight wandering, gradual sinking, and drowsiness.	Both supra-renal bodies were enlarged, lobulated, and the seat of tubercular-like deposits, both four times the natural size; the left had suppurated.	This case was recorded by Dr. Bright before the importance of dissection of supra-renal bodies was recognised.
Slight emaciation, great anæmia, extreme languor, urgent vomiting, pulse very compressible.	1 year	Speedy sinking ...	Both supra-renal bodies greatly enlarged, of irregular surface, and much indurated; natural structure lost; nucleated cells. No other important disease.	Vomiting had been so urgent in this case as to suggest the existence of malignant disease of the stomach.
No history. Died of ulcerated cancer, the bronzing being remarked at the post-mortem inspection.	Not stated.	Not stated .....	Both supra-renal bodies contained much cancerous deposit throughout their structure.	
Emaciated and feeble, much irritability of stomach.	4 mo's	Died of exhaustion in three days after admission.	Cancer of pylorus; left supra-renal body destroyed by cancer.	The extent of discoloration of skin was proportioned to that of disease of supra-renal body, one being sound.
Sickness without vomiting, weakness and loss of appetite, frequent rigors, no pain, pulse 80, feeble; body irritable.	3 mo's	Sunk gradually ...	Tubercular deposit in one supra-renal body; in the spleen also; and the kidneys were degenerate.	The degree of bronzing appears to have been proportioned to that of disease of supra-renal body, one only being affected.
Discoloration of skin not noticed until the post-mortem inspection, when disease of supra-renal body was first told. No history preserved.	Not stated.	Died from cancer..	Right supra-renal body healthy; the vein emerging from the left obstructed by cancerous deposit, and the organ itself occupied by recent extravasation of blood.	The degree of bronzing was slight, the disease of one supra-renal body being recent.
No history preserved .....	Not stated.	Died of cancer ....	One supra-renal body entirely disorganized by cancer, the other healthy.	One supra-renal body was affected, and the bronzing was slight.
Irritability of stomach with vomiting, pain across the back, great debility, emaciation, urine natural, &c.	8 mo's	Died from exhaustion consequent upon a purgative.	Both supra-renal bodies contained pus and bodies resembling hardened tubercle. There was no other disease.	The chain of morbid phenomena was very complete in this case.
Nausea, vomiting, great malaise, exhaustion, emaciation, urine healthy, blood loaded with white corpuscles.	5 mo's	Sudden exhaustion	Both supra-renal bodies atrophied and destroyed, the left contained cysts, the right solid concretions.	
Weak and low for a long time, not much emaciation.	Unkn.	From exhaustion caused by a short journey.	Both supra-renal bodies completely atrophied, and contained calcareous concretions; emphysema of lungs; fatty degeneration of heart.	
Suddenly languid, and afterwards collapsed, and died after three days; tint of skin observed for six weeks.	6 w'ks	Collapse .....	Each supra-renal body enlarged to the size of half a kidney; their structure converted into a firm tubercular-like matter, and in parts softened.	This appears to have been an idiopathic disease of supra-renal bodies, no tubercles being found in other organs.
Had also disease of knee-joint, and health rather improved until within three days of death. He remained fat and muscular.	8 mo's	Diarrhœa, followed by succession of epileptic fits, vomiting, &c.; died on fourth day of these.	Both supra-renal bodies destroyed, containing gritty, cheesy, and semi-purulent deposit. No other disease.	In this, as in case 23, a peculiar disagreeable odour exhaled from the patient for three or four weeks before death.
He died in a fortnight from delirium tremens.	3 w'ks or more.	Sunk into a typhoid state, with low delirium.	Both supra-renal bodies were converted into abscesses, but their cortical substance was not wholly destroyed; circumscribed abscess in the liver.	In this case the suppuration and inflammation of supra-renal bodies had probably been acute and recent.
Anæmic, heart's action very feeble, irritability of stomach, œdema of upper extremities.	Not stated.	Died of debility, cancer in mediastinum suspected.	No inspection .....	The œchexia was precisely that of diseased supra-renal bodies.
Great debility and wasting, but no organic disease but that of supra-renal bodies indicated.	About 6 mo's	From exhaustion..	No inspection .....	The bronzed patches indicated the patient's speedy death when there were not other alarming symptoms.

No.	References.	Sex and Age.	Occupation.	Previous Health, &c.	Early Symptoms.	Bronzing of Skin—its Degree or Absence.
20.	<i>Ibid.</i> , Dec. 15, 1855. (Mr. Startin.)	Male, 12..	At school. (Irish.)	Had suffered from abscess in the neck, and cough.	Loss of appetite, flesh; increasing languor and debility.	Copper colour general, and deepest on the face and neck.
21.	<i>Ibid.</i> , Dec. 29, 1855. (Dr. Peacock.)	Female, 14	At school...	Healthy.....	Lassitude, muddy complexion, and slight cough.	A brown muddy tint, deepest on face, arm, and shoulders; no mottling.
22.	<i>Ibid.</i> , Jan. 19, 1856. (Dr. Burrows.)	Female, 28	Married. Temperate.	Delicate.....	Menorrhagia and debility two years before the discoloration.	A fawny or yellowish brown tint, most marked on face, arms, thighs and legs; patchy discoloration in parts.
23.	<i>Ibid.</i> , Feb. 23, 1856. (Dr. Rowe.)	Male, 45..	A carter. Married. Temperate.	Robust.....	Dark spots in various regions of body. At first no illness.	Skin dusky-brown, resembling that of a mulatto; darker in some parts than in others.
24.	The Associate Journ., Jan. 19, 1856. (Dr. Budd.)	Female, 42	Married....	Good.....	A brown tinge of skin, followed by typhoid fever, after which bronzing became more marked.	Skin like that of a North American Indian; certain parts darker than others.
25.	<i>Ibid.</i> , Jan. 19, 1856. (Dr. Budd.)	Female, 40	Not stated..	Not stated.....	Not stated.....	Very dark general discoloration; large patches in mouth.
25.	Med. Times & Gaz., Feb. 23, 1856. (Dr. Thompson.)	Female, 33	Married....	Good.....	Paroxysmal pain in the abdomen; loss of strength; amenorrhœa.	Skin became suddenly and generally of a dirty-brown tinge.
27.	<i>Ibid.</i> , Dec. 22, 1855. (Dr. Rankin.)	Female, 58	Married....	Formerly very stout and of large frame.	Loss of strength and flesh	Face and hands dark-brown—"as brown as a Japanese;" other parts not seen.
28.	Trans. of Path. Society, vol. viii., p. 325. (Dr. Baly.)	Male, 18..	Baker.....	Headache, pains in the limbs, languor and debility, followed by pain in the loins.	As stated, with bronzing of the skin; pain increased by pressure on the loins; vomiting, &c.	Bronzing deep and general.
29.	<i>Ibid.</i> , vol. viii., p. 330. (Dr. Baly.)	Not stated.	Not stated..	Diseased vertebral column.	Not stated.....	No bronzing of the skin.
30.	<i>Ibid.</i> , vol. viii., p. 330. (Dr. J. Ogle.)	Female, 14	Not stated..	Incontinence of urine, scalding, containing blood and pus.	Consequent on the urinary disorder; symptoms of phthisis, under which she sunk.	No bronzing of the skin.
31.	<i>Ibid.</i> , vol. viii., p. 332. (Dr. J. Ogle.)	Male, 86..	Not stated..	Emaciation, &c. .	Symptoms of phthisis....	No bronzing of the skin.
32.	<i>Ibid.</i> , vol. viii., p. 333. (Drs. Peacock and Bristowe.)	Female, 18	Tent-maker.	Had a fall, and severe pain in the right side.	Fever, with pains in the lower extremities; œdema, &c.	No bronzing of the skin.
33.	<i>Ibid.</i> , vol. viii., p. 337. (Drs. Peacock and Bristowe.)	Male, 55..	Coppersmith	Good.....	Declined in flesh and strength; pains in back and limbs.	No discoloration of the skin.
34.	Med. Times & Gaz., Nov. 21, 1857. (Mr. Wilks.)	Female, 18	Young lady.	Delicate, but of full habit.	General debility and chronic rheumatism; lassitude and sickness.	A deep bronze tint of skin.

17. Mr. HUTCHINSON has collected a number of the cases which have been recorded, and has given a view of the chief symptoms which have characterized them. I shall notice these symptoms briefly and in succession, but independently of his account of them.—1st. *Bronzing of the skin* was observed in the majority of cases of structural lesion of the supra-renal capsules recorded by Dr. ARNISON and some others, and this physician was inclined to believe that this symptom was indicative of such lesion. Several cases have

more recently been observed where lesions of these capsules have been found without this change of the colour of the skin, and without any change whatever. Several such instances are recorded in the 8th vol. of the Transactions of the Pathological Society.—2d. *Great debility*, without any evidence of thoracic or organic disease, loss of mental energy, faintness, exhaustion, &c., were very general symptoms.—3d. *Irritability of stomach*, nausea, occasional or frequent vomitings, were also prominently observed.—4th. *Pain in*

General Symptoms, Complications, &c.	Duration of Disease.	Mode of Death.	Inspection after Death.	Remarks.
Some emaciation; great and increasing debility; oppressed aspect; urine healthy.	9 mo's	Sank from diarrhoea; a succession of convulsions just before death.	No autopsy .....	Gradually increasing prostration for four months.
Countenance expressive of great languor; emaciation; marked debility; liability to faintings, &c.	13 m's	Suddenly, from an epileptic fit.	A chalky concretion found in the medulla oblongata. The supra-renal bodies said to be free from disease.	
Appetite very bad, thirst, great debility, pain in the loins, menorrhagia, anxious expression.	7 mo's	Not known .....	No inspection.	
No material loss of health until within a few weeks of death; debility, loss of appetite, irritability of stomach supervened, failure of memory for some months, urine normal.	3 yrs.	From incessant vomitings; delirious before death.	The chief lesion observed was tubercles in the lungs. The supra-renal bodies were not examined.	A peculiar and disgusting odour a few days before death.—See case 16.
About eight months after the first bronzing she began to lose flesh and strength; harassing cough, irritability of stomach, extreme anæmia, and debility supervened.	16 m's	Sunk gradually from exhaustion.	No autopsy .....	Eight months after the change of colour began the patient had a fine healthy infant.
Anæmic and extremely feeble, sickness and vomiting.	Not stated.	Gradually sank from exhaustion.	No autopsy .....	This case very closely resembled the preceding one.
Anæmic and feeble, followed by discoloration of skin, and by a peculiar collapse.	5 w'ks	Recovered under the use of tonics, the skin becoming simply pallid.	Recovered .....	Inflammatory disease of supra-renal bodies may be conjectured.
Sinking at pit of stomach, nausea, loss of appetite, strength, &c.; secretions healthy, heart's action very feeble.	Not stated.	Still living.....	Living at time of report .....	The symptoms combine to indicate disease of supra-renal bodies.
Fever; small, feeble, and quick pulse; severe pain in loins, increased by pressure; frequent vomiting; tendency to diarrhoea; abdomen flat, empty, and tender; urine albuminous; peculiar odour of skin.	12 m's	Exhaustion, stupor, unconsciousness.	Both supra-renal bodies atrophied, and their entire structure destroyed. History and inspection fully given, with a plate.	The case very chronic, well marked, and the supra-renal bodies most completely disorganized. A very interesting case.
Disease of the vertebral column, apparently causing death.	Not stated.	Not stated.....	Both supra-renal bodies contained nodules of firm substance, gray and semi-transparent externally, and yellow and opaque internally. A great part of their proper structure unaltered.	Apparently an earlier stage of the lesions observed in case No. 28.
Phthisis, under which she sank.	Not stated.	Died from scrofulous deposits and vomicae in lungs.	Extensive deposits of crude tubercular matter in both supra-renal bodies, and in the lungs and left kidney.	No symptoms but those of phthisis mentioned.
Hectic and symptoms of phthisis.	Not stated.	Died from phthisis	Extensive deposit of scrofulous matter in one supra-renal body, the other not affected.	No symptoms excepting those of phthisis mentioned.
Tumour in left side of abdomen, emaciation, prostration, liver enlarged, the spine very prominent at the last dorsal vertebra, &c.	3 mo's	Exhaustion.....	Cancer of both supra-renal bodies, and cancerous deposits in both kidneys and in other parts.	History, case, and of the diseased appearance full and interesting.
Emaciation, care-worn countenance; retraction of gums, loss of teeth, sordes on the gums, &c.; general want of power, pains in the loins, &c.; anæmia.	4 mo's	Exhaustion....	Supra-renal bodies both destroyed, their substance being replaced by a soft white encephaloid deposit; similar deposits in the lungs.	History and morbid appearance fully detailed.
Sickness, feeble pulse; fits of incessant vomiting, returning after short intervals, for seven weeks; emaciation.	12 m's or more.	Exhaustion.....	Both supra-renal bodies enlarged, inflamed, and contained purulent matter, with gritty matter in the right.	No other visceral disease observed.

the epigastrium, back, and loins, sometimes acute, in some instances dull, or an aching increscency, was general.—5th. *Anæmia* was also generally present, this fluid being impoverished and abounding with white corpuscles, the soft solids being flabby.—6th. *Feebleness of the heart's action*, a soft, compressible, feeble, and more rarely a quick pulse, were usually observed.—7th. *A cachectic, leuco-phlegmatic, and unhealthy appearance* of the body, with or without emaciation, were frequently remarked.—8th. *A disagreeable and pe-*

*culiar odour* was exhaled from the body, in some cases, during life; and, 9th. *Several nervous and convulsive symptoms* were observed in a few instances. The tongue, the bowels, and the urine, did not present much indication of disorder. *Death* appeared to result chiefly from vital depression or exhaustion, with more or less indications of alteration of the circulating fluids. In some cases death was attributable to the disease with which the lesion of the supra-renal bodies was complicated, as to cancer, tubercular disease of the lungs,

&c. The circumstance of one of those bodies only being diseased, and the extent to which the structure of one or both had been destroyed, may be viewed as modifying or altogether altering the symptoms and the final issue.

18. ii. *The chief lesions of these bodies* which have been recorded are the following: (a) Appearances of acute inflammation and its consequences, suppuration, &c.—(b) Atrophy and total disorganization of their structure.—(c) Calcareous depositions, or fibro-calcareous concretions, with or without cysts, some of which contained a fluid puriform matter.—(d) A fibrous degeneration, with great enlargement and induration.—(e) Tubercular deposits, with great enlargement and loss of the healthy structure of these bodies.—(f) Deposits of cancerous matter, consecutively of cancer in other organs, more or less of the normal structure of these bodies being still preserved. Although these structural lesions were more frequently observed in both supra-renal bodies, yet one only was not unfrequently affected, and in a few cases a portion of the healthy structure of the diseased body was preserved. The disease of one body only, or the preservation of a portion of the structure of the organ, may rationally be allowed to modify or more manifestly alter the resulting phenomena.

19. The *diagnosis* of disease of the supra-renal bodies is very difficult: 1st. As respects the certainty with which this disease may be inferred from the symptoms present—of which, bronzing of the skin, the persistence of retchings and vomitings, the anæmia, and the weakness and smallness of the pulse, are the most characteristic; and, 2d. As regards ascertaining during life whether or no the existing discoloration is to be imputed to disease of these bodies, or to one or other of the forms of JAUNDICE, which I have described as *Green*, and as *Cachectic*, or *spurious*, *Jaundice*. (See § 46–57.) In the histories of cases of disease of the supra-renal bodies which I have perused, no such diagnosis has been made or suggested; and the appearances of the stools and the states of the biliary and urinary excretions during life, and even of the biliary apparatus after death, have been either insufficiently investigated or entirely overlooked.

20. The *prognosis* is most unfavourable, as it does not appear that any case has recovered where the skin had become bronzed or much discoloured. The prognosis may therefore be ranked in the same category as the green form of JAUNDICE described in that article. (See § 46, *et seq.*)

21. The *treatment* should be directed according to general principles, conformably with the phenomena and with the complications characterizing individual cases. These will suggest the rational indications, and the means by which they are most likely to be fulfilled, as far as this may be possible.

[In the present state of the question, the following conclusions may be legitimately drawn: 1. Disease of the supra-renal capsules is not necessarily associated with bronzing of the skin. 2. Bronzing of the skin may be produced by other causes than supra-renal capsular disease. 3. Disease, or even complete disorganization of the supra-renal capsules, may exist without giving rise to any special symptom. 4. Peculiar symptoms have been found associated with supra-renal disease in so many cases as to render it probable that the association is more than accidental, and that under certain unknown conditions a real influence may be exerted on the economy by a disease of the capsules. In a case which came under our own observation and treatment recently, the supra-renal capsules were extensively diseased, and one of them disorganized, without any change of colour in the skin.]
